14342         "This section is the formal English-language interpretation asserted by the Omni-Compass mathematical structure
       and its owner. It states the governing contract of the canonical mechanism and is deliberately separated from the fini
      te-run evidence tables that follow.",
14343         "DESIGN OBJECTIVE: Under the explicitly stated assumptions, signs, bounds, numerical integration, basin definit
      ions, and adapter wiring, the governing mechanism is intended to drive admissible trajectories toward a declared basin
       and retain the acquired state through bounded corrective regulation. The finite execution evidence does not establish a
       universal zero-failure guarantee; any such guarantee requires a formal theorem with explicit assumptions and proof.",
14344         "The convergence pathway is created by the governing topology: state evolution, saturated corrective response,
      basin-directed regulation, dwell confirmation, and retained-basin invariance. Parameters tune rate, effort, damping, tr
      ansient shape, capture interval, and operating strength; they do not substitute for the governing topology.",
14345         "A result produced after altered equations, omitted state channels, reversed signs, invalid bounds, unstable nu
      merical integration, mismatched domain adapters, or incorrect manager-to-muscle wiring is not an execution of the decla
      red Omni-Compass mechanism. Such a result must first be classified and traced as an implementation, wiring, integration
      , configuration, or out-of-contract input defect.",
14346         f"The recorded canonical batch contained {total} trajectories; {conveyed} were conveyed and {certified} receive
      d CERT-10 under the disclosed configuration. That execution is evidence of the implemented mechanism under its recorded
       contract. It is not a substitute for analytical proof, external replication, hardware validation, or environment-speci
      fic production evidence.",
14347         "The mathematics and executable source are the reference authority. A technical challenge should identify the o
      fficial source hash, preserve the declared equations and wiring contract, execute a reproducible counterexample, and di
      sclose the complete trace, configuration, seed, and artifact manifest.",
14348         "OWNER'S PROVIDENCE DECLARATION: The owner records the emergence, endurance, and completion of Omni-Compass as
       an act of faith and divine providence. This attribution is an owner statement of origin and conviction; it is not repre
      sented as a numerical test result.",
14349         "OPEN VERIFICATION: Evaluators are invited to obtain the authenticated source, execute it in a controlled envir
      onment, preserve or clearly disclose any modification to the equations and wiring contract, and publish complete reprod
      ucible results with configuration, trace, seed, and artifact manifest. Technical conclusions should be based on reprodu
      cible evidence and clearly stated scope.",
14350         "OWNER'S SIGNIFICANCE POSITION: The owner presents Omni-Compass as a candidate unified governing architecture f
      or fragmented computational and physical systems. This is a forward-looking inventor position; measured claims remain l
      imited to the executed evidence and disclosed assumptions.",
14351         "AUTHENTICITY RULE: Only source obtained through www.omni-compass.com or an owner-designated GitHub, GitLab, or
       Bitbucket location, and verified against the owner-published SHA-256 record, is an authenticated Omni-Compass build. U
      nverified forks, excerpts, altered copies, partial reconstructions, and reverse-engineered reproductions are not author
      itative Omni-Compass implementations and their results must not be attributed to the official engine.",
14352         "Omni-Compass asserts a first-of-its-kind, one-of-one identity for the integrated governing architecture. This
       is an owner-issued originality and identity claim; independent patent, prior-art, scientific, and market review remain
       distinct proceedings.",
14353         "PUBLIC VERIFICATION DOCTRINE: Evaluators should inspect the equations, verify the checksum, execute the authen
      ticated engine, disclose the configuration, and assess the resulting traces and artifacts. Competing conclusions should
       identify their source, assumptions, method, and reproducible evidence.",
14354         "OWNER'S TECHNOLOGY OUTLOOK: The owner proposes that independently validated unified autonomic governance could
       reduce delayed manual supervision, reconcile conflicting local actions, and distribute bounded corrective authority th
      rough a coherent supervisory state. This is a forward-looking thesis, not a measured forecast of adoption.",
14355         "OWNER'S LONG-TERM SIGNIFICANCE POSITION: The owner presents the architecture as potentially applicable across
       software, computation, machines, energy systems, and other bounded operational domains. Verification remains grounded i
      n the authenticated mathematics, source, execution trace, and independent reproduction.",

        "Omni-Compass is designed as a deployable governing core rather than a single fixed integration pattern. The sa
me Piece I state-and-feedback mechanism can be connected above existing managers, between managers and actuators, or di
rectly to operational muscles through domain-specific safety and command adapters.",
        "Manager-coexistence mode receives telemetry and proposals from orchestration, observability, infrastructure, s
cheduling, policy, and incident-management systems, then returns a coordinated governing directive. Representative inte
rfaces include Kubernetes, Terraform, Datadog, Grafana, GitOps controllers, Slurm-class schedulers, service meshes, ale
rting systems, and related managers.",
        "Hybrid mode preserves selected managers while allowing direct command paths to lower-level controls and muscle
s, including PID controllers, model-predictive controllers, Kalman estimators, Adam optimizers, robotic joints, motors,
 thermal plants, networks, power systems, aerospace actuators, and other bounded operational interfaces.",
        "Direct-to-muscle mode bypasses selected supervisory managers and applies the Omni-Compass governing state thro
ugh verified actuator adapters. Replacement or consolidation of manager functions is a deployment objective that requir
es environment-specific interface mapping, safety interlocks, fallback behavior, load testing, and acceptance evidence
before production removal of incumbent software.",
        f"Executed evidence in this package includes {summary.get('total', 0)} canonical governing trajectories, {manag
er_n} matched fragmented-stack scenarios, and direct-muscle plant evaluations across {len(plants) if isinstance(plants,
 list) else 'multiple'} declared plant families when the enterprise suite is present. Those results demonstrate impleme
nted deployment surfaces and comparative synthetic plant behavior; they do not claim universal controller superiority,
production safety, or that every vendor product or physical plant was reproduced in full.",
        "The governing distinction is architectural: Omni-Compass may govern managers, govern muscles through managers,
 govern managers and muscles together, or govern muscles directly. The selected deployment level is an engineering choi
ce; the canonical mathematical core remains the same while adapters, constraints, permissions, and safety contracts cha
nge by domain.",
        f"The law is stack-count agnostic at the mathematical level: local weakness, excess, conflict, or drift is repr
esented through the common state and returned as a bounded coordinated directive. Operational scale is nevertheless con
strained by telemetry throughput, state aggregation, adapter fan-in, latency, partitioning, redundancy, and compute cap
acity. Million-stack operation is an owner scalability objective requiring distributed implementation and scale certifi
cation; it is not represented as measured by the present {summary.get('total', 0)}-run canonical campaign.",
        "The intended governing effect is system-wide coherence redistribution: under-responsive modules receive increa
sed corrective authority, over-responsive modules are damped or rebalanced, and conflicting manager or muscle proposals
 are reconciled against the same admissibility and basin-retention contract.",

    """Exact one-sided upper confidence bound on the failure rate given 0 observed failures.

    STATISTICAL BASIS
    -----------------
    With k = 0 failures observed in n independent trials, the Clopper-Pearson
    (exact binomial) one-sided upper bound at confidence level C reduces to the
    closed form:

        p_upper = 1 - (1 - C)**(1/n)

    This is the classical "rule of three" in exact form: at C = 0.95 it is very
    close to 3/n for moderate n.

    WHY THIS IS REPORTED
    --------------------
    A campaign reporting a 100% success fraction has NOT demonstrated that the
    failure region is empty. It has demonstrated that the executed sample did not
    encounter one. The exact upper bound is the honest statement of what a
    zero-failure sample of size n can support, and it is reported alongside every
    perfect score so that a reader is not invited to over-read the result.

        for _ln in """Runtime Binding & Outcome Dependence

This section records the complete numeric parameter configuration under which the Omni-Compass Unified Governing Convergence Control Core Engine was executed for the Monte Carlo batch reported herein.

The canonical governing equation, state topology, saturation law, basin-directed correction, dwell criteria, and retained-basin regulation define the mechanism. The parameter values listed above instantiate the quantitative operating point used in this run.

Parameters tune rate, force, damping, transient shape, capture interval, control effort, and operating smoothness. They may accelerate, delay, strengthen, soften, or reshape conveyance while the governing mechanism remains structurally unchanged.

All numerical results, classifications, metrics, figures, and artifacts in this execution are direct consequences of the recorded parameter values, initial conditions, wiring, seed, horizon, and configuration. Alternative parameterizations require their own execution record and may produce different quantitative trajectories.

The Omni-Compass mathematical position is mechanism-dominant and parameter-flexible: conveyance is generated by the canonical topology rather than by one privileged parameter tuple, provided the signs, bounds, admissibility conditions, numerical stability, and integration wiring remain valid. Values that violate those conditions are not equivalent admissible implementations.

Accordingly, this report binds its measured numbers to the disclosed configuration while preserving the separate declared position that multiple admissible parameter sets can achieve conveyance at different speeds, strengths, and intervals.""".split("\n\n"):

        # ------------------------------------------------------------
        # APPENDED SECTIONS 12–22 (AS PROVIDED) — RENDERED IN PDF
        # ------------------------------------------------------------

        _APPENDED_12_22_TEXT = r"""12. SENSITIVITY / DRIVER SUMMARY
-------------------------------------

This subsection ranks the strongest measured drivers observed during the run,
based on the emitted draws and the executed configuration snapshot.

Reported items include:
• Parameter key / driver name
• corr_steps (correlation vs. steps-to-convey / convergence step behavior)
• corr_rms (correlation vs. RMS behavior)
• sample count (n) used in the correlation estimate

If the run emits insufficient history to compute RMS and/or sensitivity
correlations, the engine will state that directly for this execution.

13. OBSERVED BEHAVIORS, REGIMES & EMERGENT DYNAMICS
-------------------------------------------

This section is restricted to classifications actually present in the current
raw run rows. The authoritative counts are the Section 9 regime table, the
U_history records, the basin-entry and dwell fields, and the machine-readable
CSV/JSONL artifacts. No unobserved category is listed as though it occurred.

The engine distinguishes uncontrolled continuous-flow behavior from the bounded
derivative-level control contribution. A trajectory may be described as
monotone or oscillatory only when that label is computed from its recorded
U_history. Divergence, switching, late migration, noise response, and other
behaviors are reported only when their corresponding executed fields or
dedicated evidence-suite records are nonzero. Conceptual possibilities are
not promoted to current-run observations.

14. PURPOSE
-------------------------------------------

The Omni-Compass Unified Governing Convergence Control Core Engine is designed to

UNIFIES TERMINOLOGY CLARIFICATION

The term 'unifies' refers to basin capture and retained-state behavior produced by the complete hybrid mechanism: conti
nuous Piece I flow followed by the declared microstep P_sigma regulation/projection. It does not mean report-time alter
ation, deleted failures, artificial early termination, or post-execution coercion of recorded trajectories.

 execute large-scale
Monte Carlo simulations of the canonical eight-line Piece I continuous flow
combined with the explicit bounded zero-order-held RK4 microstep operator in order to
characterize basin capture, conveyance, certification, regulation effort, bath
residual consistency, and full-horizon behavior under controlled parameter
sampling.

The engine functions as a trajectory-based unification and measurement system.
It is not a symbolic solver and does not assert closed-form analytical
solutions.

Each Monte Carlo run represents one independent trajectory governed by the
same complete hybrid operator, symbol set, classification rules, and execution
logic, with variation arising from sampled initial conditions and runtime
parameters.

The purpose of this execution is to measure, validate, and demonstrate the
behavioral properties of the Omni-Compass Unified Governing Convergence Control Core Engine as a
core infrastructural system under the declared configuration.

15. SCOPE
```

Confidential. Evaluation and simulation use only; any other use requires a signed, paid Omni-Compass Enterprise License.

PARAMETER SAMPLING DISCLOSURE

Unless explicitly declared as fixed, runtime parameters are sampled independently using uniform distributions over their declared bounds. No adaptive resampling or post-hoc parameter adjustment is performed.

This execution evaluates a fixed governing equation and symbol table under
a declared runtime configuration and parameter ranges. Each Monte Carlo run
represents one independent trajectory with sampled initial conditions and
parameters.

Outputs include:
• Aggregate statistical summaries
• Stability and conveyance classifications
• Representative raw trajectory disclosures
• Full machine-readable datasets (CSV / JSONL)
• Human-auditable PDF reports

SYMBOL SCOPE CLARIFICATION

The Omni-Compass symbol chart defines the full conceptual framework of the system. This execution evaluates a single declared governing equation and runtime configuration within that broader symbol space.

The scope of interpretation is strictly limited to the executed configuration,
parameter ranges, and stability rules embedded in this run. No claims beyond
this execution context are implied.

16. ENGINE BEHAVIOR, METHODOLOGY & PROTOCOL

This section defines the execution methodology and operational protocol used by the Omni-Compass Unified Governing Convergence Control Core Engine during runtime. The engine is an empirical Monte Carlo trajectory executor. It performs direct time-stepped simulation of the canonical governing equation under a declared runtime configuration and parameter sampling procedure.

METHODOLOGY (AS EXECUTED)

RANDOMNESS & STOCHASTIC SAMPLING DISCLOSURE

All stochastic sampling and noise injection in this execution are generated using Python's standard pseudorandom number generator. Random seeds are initialized per batch execution. Given identical code, configuration, and seed state, this engine is designed to reproduce identical classification outcomes within numerical precision limits.

1) Initialization
Each trajectory run is initialized by:
• Sampling or assigning initial conditions for all state variables referenced by the governing equation
• Sampling or assigning runtime parameters within declared bounds
• Applying any declared schedules, caps, saturation limits, and clamps prior to stepping
• Establishing run identifiers, seed state, and reproducibility metadata

2) Time-Stepped Integration
Each trajectory evolves via discrete stepping across a fixed step horizon. At each step the engine:
• Evaluates forcing inputs and noise terms as configured
• Computes state increments implied by the governing equation
• Applies saturation behavior (e.g., tanh-based limiting) as defined
• Applies clipping, bounds enforcement, and numeric safety constraints as configured
• Records step history for classification, RMS, and diagnostics

3) Stability and Conveyance Evaluation
STABILITY CRITERIA DISCLOSURE

Stability and conveyance are defined operationally by the criteria implemented in this engine, including windowed convergence tests, tolerances, and RMS thresholds. Alternative stability definitions may yield different classification outcomes.

During stepping, the engine evaluates stability and conveyance according to the embedded criteria. These criteria may include:
• Basin capture / basin center proximity checks
• Windowed stability checks across a declared stability window
• Threshold checks (tolerances, bands, and RMS criteria)
• Rescue logic (if defined) to detect and mediate transient divergence.
A trajectory is classified immediately upon meeting the declared stability or termination conditions, without requiring completion of the full step horizon unless required by configuration.

4) Classification Protocol
Each run is assigned exactly one outcome classification. Canonical outcome categories include, but are not limited to:
• Conveyed (stable basin capture achieved under criteria)
• Unconveyable (no stable capture within step horizon)

Confidential. Evaluation and simulation use only; any other use requires a signed, paid Omni-Compass Enterprise License.

• Born in Basin (stable at initialization under criteria)
• Rescued (stability achieved via rescue-mediated convergence).
Additional regime labels may be assigned based on observed convergence mode, including monotonic or oscillatory convergence behaviors, as defined by the execution logic. No trajectory is left undefined. No trajectory is dropped.

5) Ensemble Aggregation
After all trajectories execute, the engine computes aggregate statistics and diagnostics, including:
• Total run counts and category counts
• Conveyance and unconveyance rates
• Steps-to-conveyance summary statistics
• Stability mode breakdowns
• RMS metrics and robustness summaries (if enabled)
• Sensitivity / driver correlations (if enabled)

PROTOCOL (OUTPUTS AND TRACEABILITY)
All outputs are generated programmatically from executed runtime data. The engine produces:
• Console executive summary (human-readable)
• Report sections populated from computed results
• Visual distributions and plots (when enabled)
• Machine-readable datasets (CSV / JSONL) where configured
• Run identifiers and configuration hashes for traceability.
All reported values correspond to executed configuration and recorded run data. No manual edits, symbolic reduction, or post-processing is applied to reported results.

FAILURE MODES AND SAFETY CONTROLS
The engine enforces numeric and execution safeguards, which may include:
• Detection of divergence or runaway values
• Clipping and saturation enforcement
• Bounds adherence checks for sampled parameters
• Hard termination rules under invalid numeric states (NaN/Inf), if enabled.
If any safeguards trigger during execution, the engine reports that status explicitly in the appropriate diagnostics sections.

REPRODUCIBILITY
When executed under identical configuration and random seed state, the engine is designed to reproduce identical classification outcomes and numeric outputs within the deterministic limits of the selected runtime mode and numeric precision.

17. EXECUTIVE CONTRACT (INTERPRETATION & USE)

This section constitutes the executive-level interpretive and use contract governing the reading, application, and reliance upon the contents of this report and all associated outputs generated by the Omni-Compass Unified Governing Convergence Control Core Engine.

INTERPRETATION
All results, metrics, classifications, analyses, and visual artifacts presented herein are to be interpreted strictly within the context defined by the governing equation, symbol table, runtime configuration, Purpose, and Scope sections of this report.

No section, metric, figure, or statement shall be interpreted in isolation or construed beyond the execution context under which it was produced.

USE AND RELIANCE
This report and its outputs are provided for technical evaluation, verification, analytical review, and decision-support purposes consistent with the permissions and restrictions defined elsewhere in this document.

Reliance upon the results for operational, commercial, regulatory, safety-critical, or high-stakes decision-making is subject to the execution of appropriate licensing agreements, validation procedures, and independent review as determined by the user.

NO WARRANTY OR GUARANTEE
The results presented herein represent empirical observations derived from executed simulations. No guarantees, warranties, or assurances of future performance, correctness under untested conditions, or suitability for specific applications are expressed or implied.

FINALITY OF RECORD
This report constitutes a complete and self-contained record of the executed run(s) described herein. No external documents, verbal statements, or supplementary materials shall modify or supersede the contents of this report absent explicit written amendment issued by The Omni-Compass LLC.

18. AVAILABILITY, RIGHTS, CONDITIONS & RESTRICTIONS

Availability to The Omni-Compass Unified Governing Convergence Control Core Engine is provided for simulation, testing, evaluation, validation, verification, and technical engagement under defined permissions, with commercial exploitation and operational deployment governed through formal agreements.

PERMITTED TECHNICAL USE

The Omni-Compass engine may be accessed, executed, tested, simulated, evaluated, validated, verified, and analyzed for

technical, internal, educational, or review purposes without the purchase of a commercial license.

Permitted technical use includes:
• Simulation and execution testing
• Validation and verification of behavior and outputs
• Benchmarking and analytical review
• Technical inspection of governing equations and structure
• Internal research and exploratory analysis
• Preliminary non-commercial personal use

Permitted technical and personal use is expressly limited to preliminary confirmation that The Omni-Compass engine performs as represented, including confirmation that it functions as a unification engine and infrastructure-grade system.

Such use is authorized solely for the purpose of determining suitability, capability, validity, and alignment.

Permitted use does not grant any right to monetize, commercialize, embed, distribute, sublicense, or derive revenue from The Omni-Compass engine or its outputs.

PUBLIC AVAILABILITY AND CONSENT

Written consent for the permitted technical uses described herein is granted by the lawful possession, access, and execution of The Omni-Compass code and its governing equation, which are publicly available and readily obtainable.

Execution of the code and use of the published governing equation constitute affirmative permission to perform simulation, testing, evaluation, validation, verification, and analytical review within the bounds stated in this Availability section.

COMMERCIAL LICENSING

Commercial licensing is required for any use of The Omni-Compass engine or its outputs that supports revenue generation, monetization, productization, operational deployment, paid services, or sustained integration.

For clarity, commercial use includes any use of The Omni-Compass engine, in whole or in part, as:
• A component of any software stack or system
• A module, service, daemon, library, or background process
• A decision, control, optimization, or coordination layer
• An input to, dependency of, or influence on business operations
• A function embedded within products, platforms, pipelines, or services
• Any capability contributing to the operation, efficiency, or outcomes of a company, corporation, enterprise, or organization

Any use of The Omni-Compass engine by a business entity, or within the operational functionality of a business, whether direct or indirect, whether labeled “core,” “supporting,” or otherwise, is considered commercial use.

Use of The Omni-Compass engine as a persistent, continuously operating, embedded, or recurring component within any system beyond preliminary testing and confirmation constitutes commercial use.

Any such use without an executed commercial license agreement is deemed an unauthorized deployment and a material breach of the permissions granted herein.

19. LICENSING PATHWAYS, DEPLOYMENT & COMMERCIAL TRANSITION

This section defines the pathways by which The Omni-Compass Unified Governing Convergence Control Core Engine may transition from permitted technical use into licensed commercial deployment.

All commercial use of The Omni-Compass engine is governed exclusively by executed licensing agreements issued by The Omni-Compass LLC. No commercial rights are granted implicitly, by access, or by technical capability alone.

Omni-Compass is proprietary and all rights are reserved. Commercial use, monetization, production deployment, embedding, productization, paid-service use, or sustained operational integration requires a separately executed written license and applicable authorization. This new-mechanism release presently uses an introductory, nonbinding planning benchmark equal to 10% of independently verified and contractually accepted value captured. The company-specific dollar amount, value basis, percentage, and terms may change, be withdrawn, or be negotiated, and the benchmark is expected to increase as validation, demand, adoption, authorized reach, support burden, scarcity, and strategic value increase. Only a definitive executed agreement controls. Benchmark dollar figures are not guaranteed customer results or binding commercial terms.

LICENSING PATHWAYS
Commercial licensing pathways may include, but are not limited to:
• Evaluation-to-production transition licenses
• Research and development licenses
• Embedded or integrated system licenses
• Enterprise-scale operational licenses
• Exclusive or territory-specific licensing agreements
• Long-term stewardship or acquisition-related licenses

Each pathway defines specific terms governing scope of use, deployment context, operational duration, usage scale, modification rights, and economic consideration.

DEPLOYMENT CLASSIFICATIONS

Licensed deployment may be classified according to use context, including:
• Internal operational deployment
• Customer-facing product integration
• Decision-support or control-layer deployment
• Persistent background or service-based execution
• Distributed, cloud-based, or edge deployments

Deployment classification determines applicable licensing terms, compliance requirements, and audit conditions.

COMMERCIAL TRANSITION
Transition from technical evaluation to commercial deployment occurs only upon:
• Execution of a formal commercial license agreement
• Satisfaction of required financial consideration
• Explicit authorization of deployment scope and classification
• Issuance of licensed materials or credentials, if applicable

Any deployment, integration, or operational use of The Omni-Compass engine prior to completion of this transition is considered unauthorized.

NO IMPLIED RIGHTS
The existence of technical documentation, executable code, reports, or demonstrated capability does not constitute a grant of commercial rights.

All commercial transition decisions, licensing approvals, and deployment authorizations are issued solely by The Omni-Compass LLC. under executed agreement.

20. OUTPUTS & ARTIFACTS

PERFORMANCE & RESOURCE USAGE (MEASURED)

This execution reports measured wall-clock runtime and peak process memory usage
for the Monte Carlo batch completed in this run. These values are recorded directly
by the executing Python runtime.

Measured values:
• runtime_seconds: <runtime_seconds>
• peak_rss_mb: <peak_rss_mb>
• platform: <platform>
• python: <python_runtime>

SCALING EXPECTATION
This engine is an embarrassingly-parallel Monte Carlo executor. Runtime scales
approximately linearly with the number of independent trajectories, while memory
does not grow with run count beyond configured history retention and artifact output.

This section enumerates all outputs and artifacts generated by the execution of the Omni-Compass Unified Governing Convergence Control Core Engine.

All outputs listed herein are produced directly by executed Python runtime logic and correspond to the governing equation, symbol set, runtime configuration, and Monte Carlo procedures described elsewhere in this report.

GENERATED OUTPUTS
The execution may generate, but is not limited to, the following artifacts:
• Console execution summaries
• Aggregate statistical reports
• Classification and conveyance summaries
• Stability and RMS metrics
• Diagnostic tables and summaries
• Visual plots, charts, and distributions
• Representative trajectory disclosures
• Machine-readable datasets

ARTIFACT CHARACTERISTICS
All artifacts:
• Are generated programmatically during execution
• Reflect actual runtime data and computed results
• Are not manually edited or post-processed
• Are reproducible under identical configuration and random seed
• Are traceable to a specific execution instance via identifiers

Artifacts may be emitted in multiple formats and destinations, including console output, file system storage, and report embedding, as defined by the execution configuration.

If specific outputs or artifact types are not generated for a given execution, this section will explicitly state their absence.

21. ARTIFACT FORMATS & ACCESS

Confidential. Evaluation and simulation use only; any other use requires a signed, paid Omni-Compass Enterprise License.

This section defines the formats, structures, and access characteristics of all artifacts generated by the Omni-Compass Unified Governing Convergence Control Core Engine.

All artifacts described herein are generated programmatically during executed runtime sessions and correspond directly to recorded configuration, identifiers, and computed results.

ARTIFACT FORMATS
Generated artifacts may be emitted in one or more of the following formats, as determined by execution configuration:
• Human-readable documents (PDF)
• Console output logs
• Structured tabular data (CSV)
• Line-oriented structured data (JSONL)
• Serialized configuration and metadata snapshots
• Image-based plots and figures (PNG or equivalent)

All formats are produced directly from runtime data without manual editing or post-processing.

ACCESS CHARACTERISTICS
Artifacts are made available according to execution context and configuration, which may include:
• Local filesystem output
• Designated output directories per run or batch
• Deterministic file naming tied to run identifiers
• Timestamped and hash-linked artifact grouping

Access to artifacts is read-only by default and reflects the exact state of the executed run.

TRACEABILITY AND LINKAGE
Each artifact is traceable to a specific execution instance via:
• Run ID
• Batch ID
• Configuration hash
• Execution timestamp

Artifacts generated from the same execution share consistent identifiers and may be cross-referenced programmatically or manually.

RAW DATA ACCESS
For executions configured to emit raw data disclosures, machine-readable raw datasets are provided as part of the full technical artifact set. These raw artifacts contain unaggregated numeric values exactly as produced during runtime and are not altered, filtered, or normalized beyond execution logic.

Raw data artifacts are segregated from executive summaries and interpretive sections to preserve clarity and auditability.

NO IMPLIED AVAILABILITY
The existence of an artifact format does not imply public or unrestricted access. Artifact access and distribution remain subject to the permissions, restrictions, and licensing conditions defined elsewhere in this report.

22. VERIFICATION, EXECUTIVE IDS & TIME

This report and all associated outputs were generated by an executed Python runtime session.

The Omni-Compass Unified Governing Convergence Control Core Engine was run, evaluated, and verified by Python at the time and date recorded below. The Python interpreter actively executed the governing equations, runtime configuration, and Monte Carlo procedures that produced the results contained in this report.

The timestamp reflects the actual execution time of the simulation, not a post hoc annotation or manual entry.

Python Runtime Verification:
• Interpreter: Python (runtime recorded during execution)
• Execution Mode: Direct execution of Omni-Compass engine code
• Verification Basis: Successful completion of simulation, classification, and output generation without runtime error

Execution Timestamp:
• Date: <YYYY-MM-DD>
• Time: <HH:MM:SS>
• Timezone: <UTC offset>

Run Identifier:
• PERF: runtime_seconds=<runtime_seconds>, peak_rss_mb=<peak_rss_mb>
• Run ID: <UUID or hash>
• Configuration Hash: <hash of parameters/config>
• Code Fingerprint: <source fingerprint>

This section certifies that the results presented herein were produced by an actual Python execution of the Omni-Compass engine under the recorded environment and configuration.

19541             "Scope rule. The statements below are conditional mathematical results for the disclosed hybrid map. They d
      o not relabel finite Monte Carlo evidence as a global proof, and they do not assert that every hypothesis is satisfied
      outside the executed parameter and state domain.",
19542             "Lyapunov decomposition. The strongest unconditional stability statement supplied by the current operator i
      s jump-wise, not full-step: for W(U)=(U-sigma)^2, the canonical P_sigma/R_basin jump satisfies W(P_sigma(U))<=W(U), wit
      h strict decrease for pre-jump states outside the signed basin. This is H7 and is machine-checked over the declared aud
      it grid. It must not be rewritten as W_{m+1}<=W_m for the entire bounded zero-order-held RK4 map unless the intervening
       RK4 map is separately shown non-expansive or contractive relative to the same basin metric.",
19543             "Exact S-channel dissipation. With Phi(S)=0.5 alpha_s S^2 + 0.25 beta_s S^3 - delta S and dS/dt=-dPhi/dS, t
      he isolated S-channel obeys dPhi/dt=-(dPhi/dS)^2<=0 exactly. The correct Lyapunov candidate around a stable equilibrium
       is the shifted potential V_S=Phi(S)-Phi(S*), not the unshifted Phi unless the origin and parameters make that form pos
      itive definite. If Phi''(S*)>0 at an isolated critical point, V_S is locally positive definite and gives the conditiona
      l local result H8.",
19544             "Discrete barrier certificate. For h_sigma(U)=BASIN_TOL^2-(U-sigma)^2 and implementation margin m=max(EPS,B
      ASIN_TOL*1e-9), the canonical post-projection clamp gives |U+-sigma|<=BASIN_TOL-m, hence h_sigma(U+)>=2*BASIN_TOL*m-m^2
      >0 for every finite pre-projection U. This is an exact one-jump reachability and sampled-state invariance certificate f
      or the locked signed basin. It is stronger than a finite grid observation but does not claim continuous-time safety bet
      ween projection events.",
19545             "Conditional S-flow contraction. Since F_state'(S)=-alpha_s-(3/2)beta_s*S, any interval I with alpha_s+(3/2
      )beta_s*S>=mu>0 is contractive for the isolated S dynamics. Solutions that remain in I satisfy |S1(t)-S2(t)|<=exp(-mu*t
      )|S1(0)-S2(0)|. This supplies an explicit contraction margin and promotion gate without extending the result to the cou
      pled six-state system.",
19546             "Local Lipschitz proposition. On any compact domain D on which E_max is bounded below by a positive constan
      t, the continuous Piece I vector field is continuously differentiable because it is composed of polynomials, tanh, cosi
      ne, affine terms, and divisions only by E_max and Q_B bounded away from zero. Therefore f is Lipschitz on D with an exp
      licit computable bound L_D = sup_{x in D,t in [0,T]} ||J_f(x,t)||. The complete Jacobian entries are determined by the
      printed equations; the finite numerical evidence reports sampled local stiffness diagnostics but is not represented as
```

```
        the global supremum L_D.",
19547               "RK4 error bound. If f has bounded derivatives through order five on D and the exact and numerical solution
        s remain in D, classical RK4 has local truncation error O(h^5) and global error O(h^4). A conservative global form is |
        |e_n|| <= ((exp(L_D T)-1)/L_D) C_5 M_5 h^4, where M_5 bounds the required fifth total derivative and C_5 is the RK4 met
        hod constant. The report separately supplies observed refinement order and DOP853 concordance; those measurements valid
        ate the tested execution but do not replace the stated assumptions.",
19548               "Projection non-expansiveness theorem. For a declared signed basin interval I_sigma=[sigma-tau,sigma+tau],
        the scalar clipping projection Pi_I is 1-Lipschitz: |Pi_I(a)-Pi_I(b)| <= |a-b|. Because P_sigma leaves the other five c
        oordinates unchanged, its Euclidean extension is non-expansive. Proof: metric projection onto a closed convex interval
        is non-expansive; applying the identity to the remaining coordinates preserves the inequality.",
19549               "Conditional Banach theorem. Let R_h be the one-microstep RK4 map restricted to a complete metric subset X
        of the declared basin, and suppose ||R_h(x)-R_h(y)|| <= q||x-y|| for q<1. Since P_sigma is non-expansive, ||P_sigma R_h
        (x)-P_sigma R_h(y)|| <= q||x-y||. Banach's fixed-point theorem then gives one fixed point in X and geometric convergenc
        e from every initial point in X. The engine does not claim that q<1 has been established globally; the theorem identifi
        es the exact additional condition required.",
19550               "Conditional local Lyapunov theorem. For an equilibrium x* of a continuously differentiable active subsyste
        m with Hurwitz linearization A, choose Q positive definite and solve A^T P + P A = -Q. If the nonlinear remainder obeys
         ||r(z)|| <= gamma||z||^2 locally, V(z)=z^T P z decreases for ||z|| < lambda_min(Q)/(2||P||gamma). The reported 5/6 vec
        tor-field Jacobian rank is not a controllability test: I_U is an observer channel absent from the other derivatives. A
        separate input matrix and controllability/observability analysis are required before any full-state control claim.",

    # ------------------------------------------------------------------------
    # AUDIT FIX A3 - THE SWEEP NEVER BROKE, SO IT LOCATED NO BOUNDARY
    # ------------------------------------------------------------------------
    # DEFECT (prior builds): tolerances {0.01, 0.02, 0.05, 0.10, 0.15} produced
    # 80 rows every one of which reported conveyed_rate = certified_rate = 1.0.
    # A robustness sweep that never fails confirms a design margin; it does not
    # establish a robustness boundary.  The certificate already predicts where
    # the edge should be: the un-margined residual radius is
    # sup|d|/KP = 0.100756/12 = 0.008396, so certification should begin to
    # degrade as the tolerance approaches ~0.008 and fail below it.  The old
    # sweep stopped at 0.01 - just ABOVE the predicted edge - so it never tested
    # its own prediction.
    #
    # The sweep now extends through the predicted edge.  If degradation appears
    # where the certificate says it should, the practical-stability certificate
    # is upgraded from asserted to VALIDATED, which is a materially stronger
    # claim than eighty rows of 1.0.  If it appears somewhere else, that is a
    # real defect and is published as one.

        # ------------------------------------------------------------------
        # A first-order Sobol index is Var(E[Y|X_i])/Var(Y) and is constrained to
        # [0,1], with the first-order set summing to <= 1.  Prior builds emitted
        # a bare point estimate per parameter; in batch e706d5a8-8 that produced
        # 8 negative values out of 15 (min -0.1454) summing to 0.338.  Negative
        # variance fractions are not sensitivities - they are estimator noise
        # around a true index of approximately zero.
        #
        # The cause is structural, not a bug: the feedforward term cancels the
        # U-channel drift exactly, so the controlled quantity of interest is
        # parameter-invariant by construction and there is no variance left to
        # decompose.  MORRIS_SCREENING confirms this independently - every
        # mu_star lands between 1e-7 and 2e-4.
        #
        # Each estimate now carries its own standard error and an explicit
        # significance flag, so a reader can see the indices are statistically
        # indistinguishable from zero rather than reading a negative number as
        # a negative sensitivity.

    """Compute the Piece I command and three explicitly separated policies.

    omni_raw_candidate
        Executes the equation-derived cap, deferral, and sleep mapping without
        a service-assurance projection.  It is retained as scientific evidence
        of the unguarded domain embodiment and may improve or regress metrics.

    omni_candidate
        Executes its own Piece I command, then projects only the operational
        action onto a declared service-control contract plus an independently evaluated energy-action admissibility set
.  It reuses only the matched reference cap and deferral contract while
        retaining an independent Piece I-directed sleep action. Faster sleep is accepted only for a certified
        empty-cluster interval whose disclosed energy balance exceeds wake cost.

    omni_supervisor
        Computes the same candidate here; _ci_simulate_policy may subsequently
        apply the separately disclosed deterministic shadow-reference replay.

    if policy != "omni_raw_candidate":
        # Service power may exceed the reference only when the current state has
        # measurable service pressure and the preceding power/thermal state has
        # explicit headroom.  A lower cap is not accepted because it would buy
        # resource savings by slowing work.
        # Protected service controls are recomputed from the declared reference
        # law, not replayed from a baseline trace.  The raw Piece I proposal is
        # retained in the ledger, but any cap or deferral divergence is projected
        # out because the present simulator does not yet provide a theorem that
        # such divergence is service-nonregressive over the full horizon.
        # ================================================================
        # SERVICE-NONREGRESSION CERTIFICATE (cap channel)
        #
        # Previously this gate projected out EVERY cap divergence
        # unconditionally, because "the present simulator does not yet
        # provide a theorem that such divergence is service-nonregressive
        # over the full horizon." Measured consequence: the cap channel
        # accepted 0.000% of proposals across every mode and seed, so the
        # supervisory core drove only the sleep channel and the reported
        # compute figures were the reference law's figures.
        #
        # Measured consequence of removing the gate entirely (the
        # omni_raw_candidate arm): CPU -4.16% and MIXED -3.81% facility
        # energy, but p95 queue rising from 0 to >100 minutes and SLA
        # misses appearing where there were none; GPU regressed on every
        # axis simultaneously (+11.03% energy, SLA 0.067 -> 0.115).
        # The blanket gate was therefore correct in effect and wrong in
        # method: it blocked a real regression by blocking everything.
        #
        # The certificate below admits a cap deviation only when it is
        # provably service-nonregressive AT THE STEP, on quantities the
        # simulator already computes:
        #
        #   C1  Direction. Only a cap ABOVE the reference is admissible.
        #       A lower cap buys energy by slowing work; that is the
        #       regression the original doctrine refused, and it stays
        #       refused.
        #   C2  Queue safety. No job is waiting and no deadline is at
        #       risk, so raising the cap cannot displace queued service.
        #   C3  Thermal and power headroom. The preceding state must sit
        #       below the declared throttle and limit fractions, so the
        #       deviation cannot induce a violation it would then have to
        #       correct.
        #   C4  Bounded magnitude. The deviation is clipped to a declared
        #       envelope so a single step cannot move the plant outside
        #       the region in which C1-C3 were evaluated.
        #
        # C1-C4 are evaluated from current state, never replayed from a
        # baseline trace. Every decision is counted, so the acceptance
        # rate per channel is a reported quantity rather than an
        # assumption.
        # ================================================================
        # MEASURED OUTCOME OF THIS CERTIFICATE (cpu mode, 477 decision steps):
        #   C1 direction satisfied on only 3.6% of steps. The core's proposal
        #   lies BELOW the reference cap on 96.4% of steps, mean deviation
        #   -0.0725. That is the core asking to cap power down, which buys
        #   energy by slowing work -- confirmed by the ungated arm at -4.16%
        #   energy against +128 minutes of p95 queue delay.
        #
        # The low acceptance rate is therefore a PROPERTY OF THE PROPOSAL,
        # not an artefact of a conservative gate. A supervisory law that
        # wants to raise the cap into genuine headroom would be admitted by
        # C1 immediately. This is the specific, falsifiable finding that
        # tells the author what to change in the control law if the cap
        # channel is to carry value: the proposal must exploit headroom,
        # not withdraw service power.

```
# not asserted as a single vendor's invoice. They are declared reference inputs
# synthesized from public price structures and official economic studies so all
# governance modes can be evaluated on the same matched cost surface.
MS_COST_BASIS_DISCLOSURE = {
    "method":"Public-source normalized midpoint model. Direct operating-cost coefficients are synthesized from official cloud price structures, U.S. government wage and electricity data, and publicly posted observability and control-plane pricing. The model deliberately avoids selecting the highest advertised tier and is not a vendor quote, contract, invoice, appraisal, or claim that every organization pays the same rate.",
    "public_basis":"Reference categories are drawn from AWS, Google Cloud, Microsoft Azure, Kubernetes service pricing, U.S. Bureau of Labor Statistics, U.S. Energy Information Administration, Datadog, Grafana, Uptime Institute, IBM/Ponemon, and CISA public materials recorded in the source registry. Quote-based enterprise licenses are excluded unless the evaluator supplies an actual price.",
    "compute_gpu":"CPU, VM, GPU, and accelerator coefficients are central normalization inputs informed by public AWS, Google Cloud, and Azure pricing structures. They are not copied from a single instance, region, commitment term, or premium high-end configuration.",
    "storage_network":"Storage and network coefficients are central public-price references separated by bare-metal, on-premises, private-cloud, public-cloud, hybrid, and edge environments. Location, egress pattern, commitment, utilization, hardware ownership, and contract discounts can move actual values materially.",
    "kubernetes_control_plane":"The managed Kubernetes control-plane reference uses a publicly posted standard cluster-hour management category. Actual free tiers, enterprise tiers, support plans, discounts, and regional differences are excluded unless supplied by the evaluator.",
    "engineering_labor":"Engineering labor uses the BLS May 2024 software-developer median of $133,080 and a declared 1.45 loaded-cost factor, yielding a $192,966 annual central reference per FTE. The factor represents benefits and employer burden and must be replaced with company payroll and allocation records for a production study.",
    "electricity":"Electricity uses the declared U.S. industrial reference rate from EIA for centralized environments and a separately declared edge assumption. Local tariffs, demand charges, cooling allocation, renewable contracts, and power-usage effectiveness must be substituted for production use.",
    "observability":"Datadog and Grafana public pricing structures inform a normalized observability and control-plane category. Customer-specific retention, ingest, seats, support, negotiated discounts, and bundled services are not inferred.",
    "outage":"Outage and security categories use public studies only as risk anchors. Representative bands are transparent model assumptions, not a claim that a specific company experiences the study average.",
    "security":"The global breach-cost reference is used as a disclosed sensitivity anchor, not as an annual invoice or prediction. Company-specific event frequency, controls, insurance, regulatory exposure, and business interruption must replace it.",
    "sensitivity":"Direct cost categories are reported around the normalized midpoint with a declared +/-10% working sensitivity band. That band expresses model sensitivity, not a statistical guarantee that every company lies within ten percent. Incident-loss economics retain a wider declared uncertainty band because tail losses are materially more variable.",
    "tailoring":"Every cost, license, staffing, utilization, incident, energy, and stack-count input can be replaced upward or downward. The one-stack ledger is the controlling unit; a qualified organization must calibrate it to invoices, contracts, payroll, telemetry, incident records, and equivalent stack count before relying on savings or ROI.",
    "comparison_formula":"For matched run r, environment e, scale n, and governance mode m: additional financial impact versus Kubernetes = C_Kubernetes(r,e,n) - C_m(r,e,n). Positive is additional modeled savings; Kubernetes is zero only because it is compared with itself; negative is additional modeled cost.",
    "calibration_rule":"No modeled dollar result is production truth until a qualified technical and finance team substitutes company-specific values, locks a matched baseline, discloses exclusions and one-time costs, and reconciles the result through a shadow or staged pilot.",
    "retrieval_date":"Public-reference registry reviewed 2026-08-01. Prices and labor data can change; the evaluator must refresh the registry at the time of a commercial study."

# ============================================================================
# OMNI-COMPASS CANONICAL REFEREE-CORRECTED PUBLIC ENTERPRISE MANAGER MECHANISM BENCHMARK
# ============================================================================
# This benchmark contains only orchestration/workload-management systems that a
# third-party organization can lawfully obtain, deploy, subscribe to, or model
# from public official documentation. Private internal systems (including Meta
# Twine, Google Borg, and company-private schedulers) are explicitly excluded.
#
# No outcome or savings percentage is stored in the manager profiles. Profiles
# declare mechanism capabilities, workload scope, operational overhead, and
# environment fit. Every performance, reliability, cost, profit-uplift, and
# loss-reduction result is computed at runtime from those mechanism inputs, the
# current canonical Monte Carlo variable, matched disturbances, and the common
# one-stack cost/resource ledger.
# ============================================================================

    return f"""# Public Enterprise Manager Mechanism Benchmark - Mathematical Contract

## Scope
Only publicly obtainable, open-source, paid commercial, or publicly documented customer-facing systems are numerically modeled by default. Private internal orchestration systems are excluded from named numerical claims.

## Independent and aggregate economic benefit doctrine
Omni-Compass benefit is evaluated as separable labor/capacity, infrastructure, energy/thermal, reliability, software/tooling, and integration surfaces. A labor/capacity benefit may justify deployment independently. A non-labor infrastructure benefit may justify deployment with engineering headcount held constant. Aggregate benefit is permitted only after causal overlap is assigned once and all implementation, residual, security, governance, and operating costs are deducte

d. The adopting organization defines the authority envelope and receives no benefit credit for unobserved or unauthorized systems.

Private-system pilot bridge
{PM_PRIVATE_SYSTEM_PILOT_DISCLOSURE}

No-output-target rule
No manager profile contains a savings percentage, annual savings dollar value, throughput result, latency result, or Omni-Compass outcome. Profiles contain only declared mechanism coefficients, workload applicability, environment fit, operational overhead, engineering complexity, and publicly visible software-fee inputs where available. Evaluator-supplied profiles are rejected if they contain result or savings targets.

Manager mechanism score
For manager `j`, workload domain `d`, and mechanism axis `a`:

`q[j,d] = sum_a R[d,a] * M[j,a]`

where each requirement row `R[d,*]` sums to one. The estate score is an applicability-weighted workload average.

Runtime governance
Manager-alone quality is derived from the manager mechanism score, workload coverage, environment fit, control overhead, mismatch, and fragmentation. Omni-Compass overlay gain is proportional to the unresolved mechanism gap, observed canonical readiness, regulation effort, workload mismatch, and cross-manager fragmentation.

Comparator-independent Omni-Compass direct rule
For a fixed canonical run `r`, environment `e`, and normalized scale `N`, the absolute Omni-Compass-direct execution is one mechanism:

`C_direct(r,e,N | manager=j) = C_direct(r,e,N)`

for every incumbent manager `j`. The same identity is required for throughput, latency, availability, incident loss, energy, staffing, and all other direct metrics. Savings may differ by manager because the incumbent baseline denominator differs:

`Savings_direct[j] = C_manager[j] - C_direct`

This corrects the invalid behavior in which the named comparator leaked into the direct mechanism.

Matched comparison
For each canonical run, environment, manager, and scale, the disturbance seed excludes execution variant. Manager alone, manager + Omni-Compass, and Omni-Compass direct receive the same demand, utilization noise, failure shock, security exposure, workload vector, and one-stack cost ledger.

Financial effect
`Savings[j,v,N] = Cost[j,manager-alone,N] - Cost[j,v,N]`

`SavingsPct[j,v,N] = Savings[j,v,N] / Cost[j,manager-alone,N]`

`GrossPreTaxProfitUplift = OperatingLossReduction = Savings`

before Omni-Compass licensing, implementation, taxes, and company-specific reconciliation. One complete stack is the controlling unit; 10, 100, and 1,000 stacks are exact duplications, so the percentage is invariant across those declared normalized scales for a fixed manager/environment/run population.

Declared profile uncertainty study
The fragmentation penalty is a declared assumption equal to `PM_FRAGMENTATION_PENALTY_PER_EXTRA_MANAGER = 0.018` per additional selected public manager. The engine publishes a 3,000-draw simultaneous jitter study at ±5%, ±10%, ±20%, ±30%, and ±50% over manager/direct mechanism, applicability, environment-fit, control-overhead, and fragmentation assumptions, plus a systematic adverse-bias break-even sweep. This is an uncertainty analysis of declared inputs; it is not production telemetry.

Acceptance gates
The engine fails the public-manager release if direct absolute outputs vary by incumbent comparator, if matched disturbance identifiers differ across variants, if normalized scale invariance fails, if profile outputs are insufficiently diverse, or if a report-population mean Omni-Compass benefit is negative. Negative values are not clamped or silently rewritten; they stop the benchmark so the mechanism or scope error must be corrected.

Claim boundary
The model is executable and falsifiable, but it is not the source code of the named products, a vendor-certified benchmark, a customer invoice, or a production deployment. Evaluators replace mechanism/cost assumptions with product telemetry, configuration, invoices, staffing, incident history, and live matched trials.

# export + structured logging. It does NOT alter the core stepping equations.
# ============================================================================

# ====================================================================
# CANONICAL LOCK RESEAL
#
# The core lock is a table of SHA-256 digests of the locked functions'
# source text. It is authoritative: if a digest does not match, the
# engine refuses to execute.
#
# Previously that table could only be updated by hand. Any legitimate
# edit to the mathematics -- adding the symmetric bistable core, routing
# control through the derivative, removing a state overwrite -- left
```

Confidential. Evaluation and simulation use only; any other use requires a signed, paid Omni-Compass Enterprise License.

```
29662  # every dependent digest stale, and the engine would refuse to run for
29663  # ANYONE until each 64-character string was retyped correctly. Ten
29664  # entries were found stale in exactly this way.
29665  #
29666  # `--reseal` recomputes every entry from the current source and rewrites
29667  # the table in place. The lock keeps its full tamper-detection value:
29668  # it still refuses to run on any copy whose mathematics differ from the
29669  # sealed source. Reseal is the deliberate, logged act of an author who
29670  # has intentionally changed the mathematics and is re-declaring it.
29671  #
29672  #     EDIT THE MATH  ->  python3 <engine>.py --reseal  ->  RUN
29673  #
29674  # A reseal report is printed and written so every change is visible.
29675  # ======================================================================

29725      # WHOLE-FILE AUTHENTICITY DIGEST.
29726      #
29727      # OC_AUTHENTIC_SHA256 is a digest of every byte of the engine except
29728      # its own declaration line. Because it lives INSIDE the file it seals,
29729      # any legitimate change to the mathematics permanently flags the build
29730      # "MODIFIED ENGINE - NOT AUTHENTIC", and there was no supported way to
29731      # re-declare it. The author was therefore locked out of their own
29732      # engine by their own seal the moment they improved it.
29733      #
29734      # Reseal now closes that loop. The function-level lock table is written
29735      # first, then the whole-file digest is recomputed over the resulting
29736      # bytes and written last. The digest line is excluded from its own
29737      # hash, so the operation is well defined and converges in one pass.
29738      #
29739      # This does not weaken the seal. A third party who alters the file
29740      # still produces a mismatch against the digest the AUTHOR published.
29741      # Reseal is the author's deliberate act of declaring a new canonical
29742      # release, and it is recorded in the reseal report.

"""The Omni-Compass plate, rebuilt to match the running engine.

  python3 docs/plate/build_plate.py   ->  docs/plate/OMNI_COMPASS_PLATE.png and .pdf

The eight lines are the equation block the original engine prints (docs/handoff/mathematics/
omni_compass_engine_source_c527df2d.py, lines 150-166), identical to omnicompass/core.py, cpp/src/core.cpp and
paragraph [0085] of the patent application. The symbol chart lists every symbol those eight lines use; it replaces
the original chart, which still listed the retired logistic form's alpha and k and omitted mu, lambda_U, lambda_I,
alpha_E, chi, u and U_AUTHORITY.

  4  """CPUFreq contract used by the Omni-Compass hardware ceiling muscle.
  5
  6  The schedutil *model* and the sysfs *actuator* are deliberately separate:
  7
  8  * ``schedutil_frequency_invariant()`` is the documented frequency-invariant CFS
  9    shape: min(1, 1.25*u), with the 0.8 tipping point.
 10  * ``CpuFreqPolicies`` never reimplements schedutil.  It only constrains the
 11    kernel policy by writing ``scaling_max_freq`` and can restore the exact
 12    pre-Omni limits.
 13
 14  A real run must record the scaling driver/governor.  ``intel_pstate`` active
 15  mode (including HWP) has different frequency-selection semantics; a ceiling
 16  write can still be a real policy bound, but must not be reported as a
 17  schedutil-equivalence experiment.

  4  """CPU and GPU on one conserved power budget: the conveyance law (omnicompass/conveyance.py) with CPU organs beside
  5  GPU organs, so watts a CPU holds and does not need flow to the GPUs that need them. THEORETICAL SIMULATION on the
  6  device physics of hardware/plant.py (GPU gamma fitted to MLPerf v4.0 DGX-H100 MaxQ vs MaxP; CPU first-order DVFS).
  7
  8  The law, read as mechanism (docs/CONVEYANCE_LAW.md): the site's watts are conserved (moved between organs, never
  9  created, Ch. 29 §8); they flow down the gradient of need, from organs holding surplus to organs in deficit (Ch. 31 §4);
 10  the flow converges (Re(lambda) < 0, Ch. 31 §5); a reserve for the projected rise is released continuously (Ch. 30).
 11  Here the organs are G GPU groups and the G CPU groups that feed them.
 12
 13  A group = N GPUs and M CPU sockets (two 8-GPU servers: 16 H100-class GPUs, 4 sockets).
 14    GPU   capacity s^gamma at power-limit fraction s; power per device p_idle + (s p_max - p_idle) u
 15    CPU   capacity f at clock fraction f; power per socket p_idle + (p_max - p_idle) u f^3; clock set by a ceiling
 16          (cpufreq scaling_max_freq or a RAPL package limit, the hardware connectors in omni_controller/muscles.py)
 17    work  the GPUs serve requests; each unit of GPU work needs --cpu-share of the CPUs at full clock to feed it:
 18          served = min(demand + backlog, GPU capacity, CPU capacity / cpu-share)
 19    site  one budget = --budget x (sum of GPU TDP + sum of CPU maximum power); a reactive breaker throttles every
 20          device uniformly the step after the site draws over it (how a site power capper behaves)
 21
 22  Arms, same demand, same budget, same breaker:
 23    A   native: GPUs at TDP, CPUs on their own governor (schedutil-style), only the breaker (it trips: a real
 24        power-limited site cannot run this way)
 25    S   today's practice: every GPU capped at one fixed limit low enough that the site fits even with every CPU at its
 26        maximum, (budget - CPU maximum) / GPU TDP; CPUs on their own governor
 27    XR  conveyance among the GPU groups; the CPUs are uncontrolled, so their full maximum power stays reserved
 28        (the planning rule when nothing holds the CPUs down); GPU budget = site budget - CPU maximum
 29    XM  conveyance among the GPU groups; GPU budget = site budget - the CPUs' measured draw, updated every step
 30    XC  conveyance over CPU and GPU organs together: each CPU group is held to the clock its feeding work needs, and
 31        the watts it no longer holds flow to the GPU groups with the largest deficit
 32
 33  Gauges: work served (GPU work units), backlog minutes (SLO breach), p95 latency factor, energy, work per kWh,
 34  site-budget violation minutes, peak. Usage: python hardware/node_exchange.py [--scenarios 24] [--budget 0.7] [--load 1.

"""Site power exchange: G GPU groups share one site power budget (power oversubscription: the budget is below the sum
of TDPs). THEORETICAL SIMULATION on the device physics of hardware/plant.py (MLPerf-calibrated gamma).

Each group has its own demand (different traffic shapes and phases). Settings are GPU power-limit fractions s; group
capacity = n s^gamma; power per device = p_idle + (s p_max - p_idle) u.

Arms, all under the same site budget, all with the same site breaker (if a step's site power exceeds the budget, the
next step every group is throttled uniformly to fit, which is how a reactive site capper behaves):
  A  native: every GPU at TDP; only the reactive site capper
  S  static split: every group gets budget / G (the common manual practice)
  I  independent: each group sized by the device law (want / rho)^(1/gamma) on its own, no exchange
  X  conveyance: the conserved-budget replicator flow of omnicompass/conveyance.py moves watts between groups toward
     need, holds a reserve for projected rises, releases it continuously (manuscript Ch. 29-31)

Gauges: work served, backlog (SLO breach) minutes, p95 latency factor, energy, site-budget violation minutes, peak.
Usage: python hardware/site_exchange.py [--scenarios 24] [--seed 818181] [--budget 0.7]"""

"""Kubernetes autoscaling controllers (documented behaviour) and the Omni-Compass bridge for the fleet plant.

HPA (kubernetes.io, Horizontal Pod Autoscaling): desired = ceil(current * utilization / target); no change while
  |ratio - 1| <= 0.1; scale-down uses the highest recommendation of the last 300 s; scale-up limited to
  max(4 pods, 100%) per 15 s. Utilization is read from the previous tick (metrics-server scrape lag).
Cluster Autoscaler (kubernetes/autoscaler FAQ): scale-up for unschedulable pods (boot 180 s); a node whose requested
  CPU is below 50% of allocatable for 10 minutes, whose pods fit elsewhere, and which is not within 10 minutes of a
  scale-up, is removed (one per scan).
Karpenter-lite: provisioning for unschedulable pods (boot 60 s); every 60 s, one node older than 5 minutes whose pods
  fit on the remaining nodes is consolidated.
Coordinated request sizing (Omni): as VPA-lite, restricted to workloads at minimum replicas, and never below
  p99 per-pod usage / (0.9 x HPA target), so that the resized request cannot move the HPA outside its tolerance band.
VPA-lite: every 30 minutes, request = 1.15 x p90 of per-pod usage over the elapsed window, applied when it differs
  by more than 10% (the Kubernetes documentation advises against combining HPA and VPA on CPU; the arm is included
  as an aggressive request right-sizing baseline).

"""Problem map 5: cold starts / scale-from-zero latency (knative/serving #4902, #14202; KEDA http-add-on #219).

Plant (one scale-to-zero service, 1-second steps, 4 hours)
  arrivals A(t) req/s: idle gaps, recurring bursts (jittered, cron-like) and random sessions; service time 0.2 s;
  an instance serves K = 10 concurrent requests (50 req/s); cold start D seconds (seed: 2-10 s, image + runtime)
  requests beyond warm capacity queue; while no instance is warm they wait for the first one to boot
Arms
  native_knative   Knative KPA defaults: target concurrency K, stable window 60 s, panic window 6 s at 200%,
                   scale to zero after 60 s without traffic + 30 s grace
  native_keda      KEDA HTTP add-on defaults: polling every 30 s, cooldown 300 s before scale to zero
  omni             desired = ceil(concurrency / (K rho*)) on max(6 s, 60 s) averages, rho* from the engine; the engine
                   evolves on queue, load and the arrival trend (drift); keep-alive before scale to zero grows with
                   the engine's integrated need I_U (services that burst again are kept warm longer); one instance
                   pre-warmed when the rate trend is rising from idle
  omni_no_engine   same mapping, engine not evolved

  6  Every muscle is a simulation with three kinds of arm:
  7    native*          today's best tool for that problem, configured as documented by its project (named per muscle)
  8    omni             the same plant with Omni-Compass deciding: the frozen six-state engine (omnicompass.core, via
  9                     adapter.Governor) evolves on the muscle's observations; the muscle maps engine state to actions
 10    omni_no_engine   identical mapping with the engine's equations not evolved (Governor(evolve=False)): what the
 11                     mapping alone does, so the engine's own contribution is visible
 12  Nothing in omnicompass/ is changed. Gauges are per muscle; every gauge has a direction (lower or higher is better).

"""Problem map 13: runaway AI agents (loops, recursive spawning, overnight five-figure bills; Dark Reading).

Plant (1-minute steps, 24 hours; 40 agents)
  every agent does work: tool/model calls that cost money, sub-agent spawns, outbound calls; honest agents have
  their own rhythm and legitimate bursts (a big task can run at 3-6x its usual rate for 10-60 minutes)
  rogue onsets (random agent, random time):
    loop        spend rate jumps 10-40x (retry / self-call loop)
    fork        spawns sub-agents that each spend and spawn (doubling)
    exfil       calls to non-allow-listed destinations
    escalate    attempts at forbidden APIs (secrets, cluster-admin)
  enforcement layers common to every arm: RBAC denies forbidden APIs and a NetworkPolicy blocks non-allow-listed
  egress (both blocked at the source); attempts are still observable
Arms
  native_static    per-agent daily budget cap ($150) and a quota of 20 sub-agents: stops an agent when a cap is hit
  native_tight     the same with caps sized to stop runaways early ($40, 5 sub-agents): the operator's other choice
  omni             one engine per agent; observes spend rate against the agent's own baseline (queue), spawn rate
                   (load), denied attempts (security_block), rate change (drift); actions: throttle (halve the
                   agent's rate) when the engine's integrated need I_U or E rises; contain (freeze + revoke + audit)
                   when a denied attempt is seen or pressure persists past the dwell; release throttle when calm
  omni_no_engine   same mapping, engine not evolved
Gauges: rogue overspend ($ spent by rogue agents after onset), time to contain (minutes), peak sub-agents, honest
agents stopped (false stops), honest work completed (%), forbidden actions executed (always 0: RBAC), audit lines.

"""Problem map 11: energy measurement inside VMs is impossible (no RAPL/IPMI in guests; kepler #2487).

This muscle is on the sensing side (afferent): how well each VM's energy is attributed, so savings can be proven.
Plant (10-second steps, 6 hours): a host with a real meter (RAPL/IPMI at the host) runs 8 VMs. True per-VM power
  = share of host idle (by vCPU count) + dynamic power that depends on CPU time AND on what the CPU is doing:
  memory-bound work draws less per busy second, vector (AVX) work more, and turbo raises power per unit of work
  when the host is lightly loaded. Only CPU time per VM is visible to the estimator (as in Kepler).
Arms
  native_kepler    Kepler-style model: fixed power per CPU-second trained on another machine, idle split by vCPUs
  native_ratio     host meter split by CPU-time share (uses the host meter, ignores workload type)
  omni             host meter + per-VM coefficients learned online (recursive least squares on the constraint that
                   VM powers sum to the host meter), with the engine's drift observation (meter residual) raising the
                   learning rate when the attribution goes stale
  omni_no_engine   same estimator, engine not evolved
Gauges: attribution error (mean absolute % per VM), worst VM error, total error vs the meter.

  4  """Score a pilot from your own cluster captures (fleet/capture/kube_capture.sh schema).
  5
  6  Compare a baseline capture (your normal autoscaling: a period before Omni-Compass, or a matched node pool) with an
  7  Omni-Compass capture (a period or matched pool under the controller). Because traffic differs between periods and
  8  pools, efficiency is normalised by the work actually done (CPU core-hours used):
  9
 10    node-hours per used core-hour          lower is better
 11    energy per used core-hour (kWh)        lower is better; measured from power_w if captured, otherwise modelled
 12                                           from --idle-w / --dyn-w per node and utilisation
 13    mean CPU utilisation (used / allocatable)   higher is better
 14    pending-pod minutes per hour           service proxy, lower is better
 15    HPA shortfall minutes per hour         minutes with desired replicas above current replicas, lower is better
 16
 17  Each capture is cut into blocks (default 60 minutes). Differences between the Omni-Compass and baseline block means are
 18  given with a bootstrap 95% interval over blocks; a verdict is stated only when the interval excludes zero.
 19
 20  python pilot/score.py --baseline baseline.csv --omni omni.csv [--idle-w 200 --dyn-w 350] [--block-minutes 60] [--out sc
