The Omni-Compass: source code

Owner and author: The Omni-Compass LLC
Version (git commit): 68df925d0367, omni-v1 (engine ccc7fbdf8b312ed7)
Printed: 2026-10-05

Complete source listing.
860 source files, 201,112 lines, 3,307 pages of source in the full listing.

Languages: Python, C++, shell, YAML (GitHub Actions workflows).
Order: the engine (omnicompass/), the controllers (omni_controller/), the C++ twins (cpp/), the fleet and realms models, tools, scripts, deployment, tests, workflows.

"""The Omni-Compass, computed.

I read my own state on the compass every decision and say where I am, in the compass's own terms.

The wheel (Chapter 29). My deviation E, scaled by its ceiling E_max, runs along the horizontal; its rate of change runs
along the vertical. A reading is a point on that wheel. Its heading is measured clockwise from north, as on the face:

    +   A     0 deg   rising through rest
    ■   Δ    45 deg   expansion: above rest and rising, exchange under way
    >   B    90 deg   peak extension: the turn, where the metric flips (k -> -k)
    ■   Λ   135 deg   dispersion: above rest and easing, the ceiling holds
    -   Ω   180 deg   falling through rest
    ≈   Π   225 deg   compression: below rest and settling into the basin
    <   Γ   270 deg   deepest compression: the turn at the floor
    ❖   Ψ   315 deg   re-alignment: below rest and rising, ignition ahead

The four quadrants are the strokes of the closed circle (Chapters 29-30):
    I   Expansion     above rest, rising
    II  Dispersion    above rest, easing
    III Compression   below rest, falling
    IV  Re-alignment  below rest, rising
The wheel turns I -> II -> III -> IV -> I. Crossing from IV into I is ignition; the turn at peak extension is the
metric flip. The state is continuous through every crossing: nothing switches off, nothing restarts.

The rim carries the 24 letters in their places on the face, 15 degrees each, clockwise from A at north.

The axle is the structural basin S. Its rest point S* solves equation (6): delta - alpha_s S - (3/4) beta_s S^2 = 0.

Closing the circle (Chapter 1, the Unified Circle Principle):
    X' = G(X),  X(0) in Omega           Omega is the living band: every level inside [0.05, 0.95]
    G(X) . n(X) <= 0 on the boundary    at a boundary the next move points inward, never outward
    grad L(X) . G(X) <= 0               the ledger L, the engine's composite storage over all six states
                                        (omnicompass.storage.composite_V), descends when nothing is forcing it
    => lim X(t) in M*                   the state settles into the basin
I check all three every decision and report them. The ledger may rise while outside load forces me; I report that as
forcing, never hide it.

"""The compass: one smooth law for every muscle, and the plug every muscle is wired through.

A muscle is a plug with one wire in and one wire out. The plug reads its meters and writes its lever; all the
thinking is here, in the brain, written once for every muscle.

The plug (Plug)
  read      the service reading (response time, temperature, queue) and the lever as it stands
  write     one value; the plug clips it to the cover, sends it, and reads back what the device took
  restore   the lever back to the snapshot, the value read once before the first write; it never moves after that
  one writer if the lever is found at a value the brain did not write, someone else owns it: the brain stops writing
            and leaves that value alone (restoring over it would fight the new owner)

Two bands
  cover     the outer band, the lever's hard range (the device's or the buyer's lowest and highest setting); every
            write is clipped to it, so nothing the math does can set the lever outside
  compass      the service reading as a position in its band, 0 to 1 (0: calm, 1: the service line); the brain pulls it
            to the bottom of the compass, the center (0.5 by default); the walls run to 0.05 and 0.95, and the last 5%
on
            each side is cushion (10% in all) before the line

The force (CompassLaw.force), the physics of a ball in a compass with the right friction
  pull      K_P x (position - center): gentle near the bottom, harder up the walls
  push      K_D x velocity: whatever is shoving the position (a load rising, heat building) is met by an equal and
            opposite push; it is also the friction that stops the ball sloshing past the bottom (with K_D chosen for
            critical damping it glides to the center and stops, no overshoot, no ringing)
  smooth    the force is A x tanh(raw / A): a spring near the center that bends over and flattens into its maximum A,
            never a corner, never a hammer; the same shape the engine already uses for v_eff (omnicompass/core.py)
  fail up   past the 0.95 wall the up side goes to its full force at once, and the down side may not act until the
            position is back inside the compass

Two forces (antagonist pairs)
  up        a positive force adds capacity, power, cooling or speed (scale out, raise a clock, start a chiller)
  down      a negative force takes it back (scale in, lower a limit, warm a setpoint)
  each side has its own gain (lever units per unit of force), because adding and taking back do not cost the same;
  a muscle with two wires (a GPU's clock range and power limit) gives each side its own lever; a one-wire muscle
  carries both directions on its one lever

The frozen engine (omnicompass/core.py) and its proofs are untouched; this is a separate law, run as its own arm.

"""Conveyance law: moving a conserved budget ("juice") between organs.

Manuscript sources (interpretation of the English, not only the symbols):
  Ch. 29 §8   E_system = E + U + S + B, dE_system/dt = 0 over the cycle: "Energy redistributes. Energy reorganizes.
              Energy does not diverge."                                    -> the budget is conserved, only moved
  Ch. 31 §4   "When E grows locally, B increases to distribute gradients." -> flow runs down the gradient of need
  Ch. 31 §5   stability requires Re(lambda_i) <= 0                          -> the flow must provably converge
  Ch. 30 §5-7 ignition is a "redistribution surge ... controlled release", with state continuity (no discontinuity)
                                                                            -> the reserve is released continuously
  Ch. 29 §6   compression: "backpressure develops through S ... structured inward rotation"
                                                                            -> surplus is pulled back smoothly

The law. Organs i hold allocations a_i of a budget A (watts, cores, ...), have need d_i (the budget that would serve
their work at the engine's utilisation target rho), and a deficit ("local deviation")
        e_i = d_i / (rho a_i) - 1        (> 0 needs juice, < 0 holds surplus)
The redistribution mediator moves budget by the replicator flow
        da_i/dt = kappa a_i (e_i - e_bar),       e_bar = sum_j a_j e_j / A
Properties (proved in docs/CONVEYANCE_LAW.md, checked in tests/test_conveyance.py):
  P1 conservation      sum_i da_i/dt = 0 exactly: the budget is moved, never created
  P2 gradient flow     it is the Shahshahani gradient of F(a) = sum_i (d_i / rho) ln a_i on the simplex sum a_i = A;
                       F is strictly concave, so F rises monotonically (Lyapunov function)
  P3 convergence       unique equilibrium a_i* = A d_i / D (D = sum d_i): every organ at the same deficit e*,
                       reached exponentially: da_i/dt = (kappa/rho)(d_i - a_i D/A), rate kappa D / (rho A), and the
                       linearisation has eigenvalues -kappa D/(rho A) < 0 (Re(lambda) <= 0, Ch. 31 §5)
  P4 bounds            organ floors and ceilings (device minimum, TDP) are kept by projection; budget an organ cannot
                       take because it is at its ceiling returns to the others (water-filling), and budget left over
                       when every organ is at its need is held back as reserve, not spent
Reserve (Ch. 30 surge): R = the budget needed to cover the demand rise the rate tracker projects over one actuation
delay; released continuously to organs whose deficit stays positive after the flow."""

"""The kill switch (the master switch): one OFF for the whole harness, not one muscle at a time.

Its purpose is security: if anything gets into Omni-Compass's brain and tries to drive a system for its own ends, or
anything rogue happens, one switch in a human hand turns Omni-Compass's governing off everywhere at once. It is not
the reset (the brake held to the floor at the end of a run, which hands one governor's settings back).

Every Omni-Compass governor on a machine (the Kubernetes controller, the GPU governors, any muscle they drive) obeys on
e
switch, in a human hand:

  OFF   the switch file exists (OMNI_MASTER_OFF, by default /tmp/omni-compass/OFF). Every running governor sees it at i
ts
        next decision, puts every setting it ever wrote back to the value it read before its first write, reads each on
e
        back, writes its last audit line and exits. No governor starts while the switch is OFF.
  ON    the switch file is removed. Nothing restarts by itself: a governor runs again only when someone starts it.

The switch is also pulled from the command line, which signals every registered governor at once so none waits for its
next decision:

  python3 tools/omni_switch.py off [--reason TEXT]    turn the whole harness off, wait for every governor to restore
  python3 tools/omni_switch.py on                      allow governors to be started again
  python3 tools/omni_switch.py status                  OFF or ON, and every governor running

A governor that cannot read the switch (a filesystem it cannot reach) treats that as OFF: when in doubt, hand back.

If a governor dies without handing back (killed outright, the machine crashed, it hung), nothing it wrote may be left
in place. So every governor records, before its first write, the exact commands that put every setting back, and
renews a lease every decision. The watchdog finds any governor whose process is gone or whose lease is older than its
limit and runs those commands for it:

  python3 tools/omni_switch.py watchdog [--stale 60] [--every 10]    keep watching (run it as its own service)
  python3 tools/omni_switch.py watchdog --once                       one pass

"""Math-driven actuation: the Omni-Compass equations move the system directly.

The frozen governor (adapter.Governor) evolves the equations open-loop (u = 0) and reads only a few derived numbers.
Here the equations are closed-loop and their own quantities ARE the actuator commands. No equation is changed; the
integrator, parameters and observation map are the frozen ones (omnicompass/core.py, omnicompass/adapter.py).

Per decision
  1. sense      x <- assimilate(x, observe_vector(telemetry))                    (the frozen observation map)
  2. evolve     x <- macro_step(x, target = +1, macro_dt = clock)                equations (1)-(7) with equation
                (2)'s controller ON: u = clip(-f_U(x) + 12 (1 - U), -25, 25) holds the healthy basin U = +1
  3. read the   effort  w = integral |u| dt / (25 clock)   in [0, 1]: how hard the math had to work to stay healthy
     math       need    I_U                                equation (3): unrelieved need, slow memory
                tide    B, B_dot                           equation (7): the bath, second order, anticipates
                drive   v_eff                              equation (4): the tanh-bounded drive
  4. actuate    capacity   n = ceil(fit (1 + g_w w + g_I max(0, I_U) + g_B max(0, B_dot))) machines
                           (released one at a time only while w <= w_release: the math reports calm)
                pods       HPA target rho = clamp(rho0 - k_w w - k_I max(0, I_U), rho_min, rho0)
                power      cap = clamp(1 - g_cap max(0, B) + 2 w, cap_min, 1)   (the bath lowers power only when calm)
  clock: engine time advanced per decision. It sets how fast the math moves relative to the system: the bath's
  natural period is 2 pi / omega_B = 6.28 engine units, i.e. 6.28 / clock decisions.

"""Infrastructure component catalog and fleet overhead model.

Each component records its role, deployment pattern, resource footprint, the source of that
footprint and its evidence status, and its classification under the keep-or-remove rule:

  decision       control logic whose function the governor performs      -> candidate for removal
  observability  telemetry and storage for humans, audit and control     -> retained; control path replaced by direct s
ensing
  execution      machinery that performs the work                        -> retained
  security       cryptography, identity, policy, runtime detection       -> retained unless a stronger guarantee is pro
ven

Evidence status:
  measured       benchmark or production measurement published by the source
  documented     formula or default published in official documentation
  example        request values from a published example manifest
  assumption     modelling assumption; parameter exposed for sensitivity analysis

Energy per resource follows the Cloud Carbon Footprint method:
  W = vCPU * (W_min + u * (W_max - W_min)) + GB * W_mem, scaled by PUE.

"""Nervous system: one engine, many muscles.

Each muscle is a connector with five parts (domain map):
  afferent  sense
  engine    shared six-state field (not duplicated)
  efferent  push
  reflex    shield / bounds before push
  kill      return that muscle to its native controller

Status:
  wired     sense and push are executed in this tree
  sensed    telemetry is accepted; push is not issued
  open      connector registered; no plant; no push

This module does not replace adapter.Governor. It sits around it:
afferents merge into the observation vector the governor already understands;
efferents are tagged by muscle so a kill is per-nerve, not a mystery write.

==== omnicompass/nervous_system.py (158 lines) ====

```
"""The supervisory nervous system: one evolving engine state grants authority to every organ family.

Omni-Compass does not replace the specialist controllers. Each keeps its own mechanism:
- the HPA and VPA size pods;
- the Cluster Autoscaler and Karpenter size node pools;
- Linux schedutil picks CPU frequency;
- NVIDIA DCGM manages GPUs;
- rollout controllers and routers do their own work.

The nervous system decides, from one shared state, the envelope inside which each of them may act.

Inputs, all from the six-state engine (omnicompass/core.py, via the governor), and nothing tuned per organ:
  kappa  convergence   = 1 if push <= push_release, else push_release / push. This is the equation-(2) gate made
                         continuous: the further the engine is from its basin, the less it may give back.
  h      basin health  = clamp((U - U_gate) / (1 - U_gate), 0, 1)
  sigma  stress ratio  = S / S*, where S* solves delta - alpha_s S - (3/4) beta_s S^2 = 0 (equation 6)
  nu     unmet need    = max(0, I_U) (equation 3)
  calm                 = kappa * h * (1 - clamp(sigma - 1, 0, 1)) * (1 - clamp(nu, 0, 1))
                         in [0, 1]; 1 means fully settled

Authority per organ:
  expand     may the organ add capacity or performance. Always yes, except during a security hold.
  contract   may it give capacity or performance back. Only when calm >= the organ's reversibility threshold
             (theta_pods 0.5, theta_nodes 0.7: a node costs a boot to reverse) and the SLO is clean.
  step       fraction of the organ's surplus it may shed this decision. Equals calm.
  envelope   for continuous organs, the allowed range:
               cpufreq ceiling (fraction of cpuinfo_max) in [1 - 0.35 calm, 1];
               GPU power limit (fraction of max) in [1 - 0.30 calm, 1];
               site power cap in [0.65, 1];
               traffic-shift fraction in [0, 0.5 calm];
               cooling supply-air setpoint (C) in [18, 18 + 9 calm].
             Heat above 0.96 forces the frequency and GPU ceilings down to 1 - 0.35 x excess.
  batch      admit held work only if calm >= 0.5 and power stress < 0.9; pause pausable work if sigma > 1, power
             stress >= 0.95, or heat >= 0.96.
  rollback   the engine's rollback authorisation (S high, U falling, or a security hold).

Global rules, applied last:
  - observe: every authority is computed and logged; execute is False everywhere.
  - kill: no authority at all.
  - security hold: no capacity organ may expand. Cooling is the one protective organ: "expand" there means more
    cooling, which adds protection and no capacity, so it stays allowed.
The safety shield (omnicompass/shield.py) stays downstream and can still veto any action.

  I2 bounds     node targets lie in [minimum_nodes, maximum_nodes]; power cap in [0.65, 1.0]. When the current node
                count is itself outside the bounds and the rate limit I5 forbids reaching them in one step, the target
                must move toward the bounds (the only admissible direction): n > max -> max <= t < n, n < min -> n < t <= min
  I3 coherence  an action set never both expands capacity and tightens the power cap
  I4 power      no node addition whose projected power stress exceeds power_limit:
                projected = observed_power_stress * (n + k) / n
  I5 rate       node change per interval bounded by max_node_step

The shield is a runtime monitor: it guarantees the invariants for executed governor actions
under the observed state. It does not certify the plant model.

"""Speed-first allocation: the frozen six-state engine, a law that never trades response time for energy.

The frozen fleet law (adapter.AllocationLaw, FLEET_MODE) uses one number, rho*, both as the HPA target (how busy each
pod may run) and as the node-sizing target (how busy each machine may run). Saving machines therefore always meant
running pods hotter, which is where response time was lost. This law separates the two:

  pods      HPA target = rho* from the engine (equation: rho* = clamp(rho0 - kI I_U - kE E, rho_min, rho0)), with
            speed constants (rho0 near the latency knee) and the response-time nerve feeding the queue observation
  machines  sized to what the pods ask for, not to how busy they are:
            n_up   = ceil(requests / (cores * ALLOC) * (1 + headroom_up)) + ceil(kq * q * n)
            n_keep = ceil(peak requests over the last `window` decisions / (cores * ALLOC) * (1 + headroom))
            added at once when n < n_up (a pending pod costs response time);
            removed one per decision only when n >= n_keep + band for dwell decisions, no sooner than after_add
            decisions after an addition, and only while the engine's equation (2) push <= push_release
  ahead     while requests are rising, n_up += ceil(antic * trend * n), trend = relative rise over antic_lag
            decisions (anticipation: machines boot before the pods that need them are created; antic = 0 disables)
  power     cap = 1 whenever work is waiting or pods are busy above cap_busy; otherwise cap_idle
            (a cap slows service: S = S0 / cap, so capping a busy machine always costs response time)

The engine state (E, U, I_U, S, B, B_dot) is evolved by omnicompass.core unchanged; only this mapping is new.

"""The verdict: Omni-Compass moves a knob only where it measures that the muscle is no worse for it.

Omni-Compass sits on top of a muscle that already works (a card's firmware, an autoscaler, a chiller's loop). It does n
ot
replace that muscle, and it has no reason to move the muscle's knob unless moving it costs the muscle nothing. The
verdict is how the brain finds that out, on the muscle itself, before it acts and again from time to time:

  steps     the knob's settings from native outward, in whole steps (step 0 is native: the muscle as it runs alone)
  cost      what each setting costs the muscle's own work, measured per piece of work (a card: the milliseconds it spen
ds
            on one request, the wait in the queue left out, so more traffic is never mistaken for a slower card)
  probe     while the service is calm, a paired trial: first the knob at native until min_samples pieces of work are
            measured (the reference, fresh, under the same traffic), then at one step past the deepest step already
            allowed until min_samples more are measured
  judge     the trial step's median cost against the reference's: no higher (within the measurement's resolution,
            tolerance) and the step is allowed; higher and it is refused, the knob goes back, and that step is not trie
d
            again until recheck decisions have passed (the work may have changed). A trial that sees the service leave
            calm is abandoned, and the knob goes back at once
  allowed   the compass may move the knob only between native and the deepest allowed step; where no step is allowed, t
he
            verdict is "left native" and the knob is never moved

  stepwise  for a knob that is slow to move back (a machine given back takes minutes to return), incremental=True runs
            the reference at the deepest step already allowed instead of at native, and judges the trial step against
            both that reference and the cost first measured at native, so steps can never add up past the allowance

The verdict never makes the knob more aggressive than the law: it only narrows where the law may go. Every probe and
every judgement is returned to the caller for the audit.

```
"""Omni-Compass live controller for a real Kubernetes cluster.

Modes
  observe   read the cluster every interval, run the fleet-mode governor in OBSERVE, log every decision; no writes (default)
  target    additionally patch each HPA's CPU averageUtilization to rho* (bounded, rate-limited); the Cluster Autoscaler and
            all node management remain unchanged
  nodepool  additionally size one node pool to the governor's recommendation through --node-scale-cmd, a command template
            such as "aws autoscaling set-desired-capacity --auto-scaling-group-name POOL --desired-capacity {n}"; the
            Cluster Autoscaler must not manage that pool
Laws (--law)
  governor  (default) the engine's allocation law sets the HPA target (rho*) and the closure law or the governor sizes the pool
  compass      the compass law (omnicompass/compass_law.py) holds the service in its band, read as the GPU compass reads it: the mean
            response time of the latency window between the bare service time (a tenth of --slo-ms) and --slo-ms, held at
            --compass-center (0.4); p95 at or past the SLO, a blind sense or pods waiting for a place read as past the wall. Its push and pull move two levers: each HPA's CPU target inside its cover (from 60% of the
            operator's target up to the operator's own, never tighter than native, so it only ever adds pods and gives them
            back) and the node pool (one machine back only while the force is clearly down, the position below the center
            and the nervous system's release gate open; past the 0.95 wall, one machine up at once). The verdict
            (omnicompass/verdict.py, stepwise) decides how many machines may be given back at all: while the service is
            calm, one more machine is given back on trial and the response time of the requests served without it is set
            against the requests served just before and against the cluster as it ran on its own at the start; at most
            --allow slower and that machine stays given back, slower than that and it is taken back and not tried again
            for --verdict-recheck decisions. Where no machine passes, the pool stays as the cluster runs it alone. The
            six-state engine still runs every decision: it grants the authority, feeds the release gate and the compass,
            and is audited
Safety
  every node action passes through the shield (bounds, step limit); the recommendation never falls below what the CPU
  requests of running and pending pods, or current usage, need, and capacity required by that floor is added in one step
  (the step limit applies only to the governor's own adjustments); --dry-run logs intended writes without executing them; creating the kill file (or
  setting OMNI_KILL=1) restores every HPA target this controller changed, runs --node-restore-cmd if given, and returns to
  observe; every decision and action
  is appended to the audit log.
Requires kubectl on PATH with access to the cluster (metrics-server for kubectl top).

  4  """Omni-Compass on one GPU through two wires: the compass law (omnicompass/compass_law.py) on a real card.
  5
  6  The card keeps its own control: NVIDIA's firmware still boosts and still protects the chip. Omni holds two settings the
  7  card already accepts, and nothing else:
  8    up wire    the clock ceiling: how high boost may climb (nvidia-smi -lgc MIN,MAX; -rgc resets it)
  9    down wire  the power limit: the lid above what that ceiling draws (nvidia-smi -pl W)
 10
 11  Every decision (--interval seconds):
 12    read      nvidia-smi: power.draw, temperature, utilization, power.limit, clocks.sm; the workload's response times
 13    position  the service as one place in its compass, 0 calm to 1 the line: response time only (the mean over the last
 14              --latency-window-s, between a tenth of the line, the bare service time, and the line; the 95th percentile a
    t
 15              or past the line, or a failed request, is past the wall). A card that is busy is doing its work; being busy
 16              is not a breach and is not read as one
 17    native    what the card does on its own, learned from its own meter before the compass may lower anything: while the
 18              ceiling is at the top and the card is busy, its clock and its draw (the clock its own power limit holds it
 19              at, and what that costs). Until --learn-samples busy readings are in, the ceiling stays at the top
 20    race      while the card is saturated (utilization at or over --race-util: work is waiting), the ceiling goes to the
 21              top and the lid to the start limit, so a burst is served at full speed; the compass paces only the slack
 22    force     the compass: pull to the center, push against what is rising, tanh-bounded; past the 0.95 wall: fail up
 23    verdict   how far the ceiling may go (omnicompass/verdict.py): while the service is calm, a paired trial: the ceiling
 24              at the top until --verdict-samples requests are measured, then one 15 MHz step past the deepest step
 25              already allowed until as many again are measured; the card's own time on each request (the workload's
 26              service_ms, the wait in the queue left out) is compared: at most --allow slower and the step is allowed,
 27              slower than that and it is refused and not tried again for --verdict-recheck decisions. Where no step
 28              passes, the ceiling stays at the top: the card runs as it does alone
 29    law       down gain 0.0125, the compass's center at 0.4, the speed floor at the card's own busy clock (amendment 8)
 30    steady    while the card is saturated against its own power limit (work waiting and the draw at the limit), the
 31              firmware boosts a step, hits the limit and is knocked back: a sawtooth. The ceiling is then held at the
 32              card's own busy clock under that limit (what the sawtooth averages to), so the same watts serve the work
 33              without the knock-backs (amendment 9). Only under an operator's cap (the start limit under the card's
 34              factory limit, amendment 12): on the card's own limit the firmware's boost is left to serve the burst. It
 35              never holds under that clock, and blind always fails up
 36    write     up wire: the ceiling moves by the force (fast up, gently down), inside its cover: from the card's own busy
 37              clock (never slower than native while there is work) to the top; down wire: the lid at the card's own busy
 38              draw plus --lid-headroom, never under it and never over the start limit, inside the declared envelope;
 39              fail up: ceiling to the top and the lid to the start limit at once
 40    guards    blind (meters unreadable, response times stale): fail up; heat (the card reports a thermal or hardware
 41              slowdown): never tighten; one writer: a power limit neither mine nor the start means another writer, so
 42              observe only from then on and exit 5; read-back: every write is read back
 43    restore   on exit, kill file or SIGTERM: clocks reset (-rgc) and the power limit back to the start, read back
 44
 45  The audit (--audit) carries the same records the bench reads from the one-wire governor (snapshot, decision with
 46  telemetry and decided_by, write and actuator for each power-limit write, restored), plus clock_write records.
 47  Exit: 0 clean, 3 restore failed, 4 a write refused, 5 another writer.

==== omni_controller/gpu_governor.py (529 lines) ====

```
"""Omni-Compass on one GPU box, no Kubernetes: the engine reads each GPU's own meter and may lower its power limit.

Every decision (--interval seconds), for each GPU in --gpus:
  sense     nvidia-smi: power.draw, temperature.gpu, utilization.gpu, power.limit (the device's own readings)
            the workload's response-time file (--latency-file, elapsed_seconds,latency_ms,ok) if given
  engine    the Omni-Compass governor, throughput law (omnicompass/adapter.py): load = utilization, power stress =
            draw / the limit found at start, heat = temperature / --temp-limit, queue = response-time pressure.
            Its directive power_cap is the share of the start limit the GPU may draw.
  shield    limit = max(cap x start limit, draw x (1 + --headroom), --min-share x start limit, the device's minimum
            limit), never above the start limit; whole watts; a change under --min-change-w is not written.
            --min-share bounds the slowdown: a card held at that share of its limit runs a burst only a little slower.
  busy gate utilization (smoothed over decisions) at or above --util-gate: the start limit. A busy card is the
            bottleneck; slowing it grows the queue faster than it saves energy. The cap returns once utilization is
            back under the gate less --util-band.
  reflexes  a blind sense (nvidia-smi unreadable, or the response-time file stale or empty): the start limit, at once
            a response-time breach (p95 > --slo-ms), and for --slo-clear decisions after it: the start limit, at once
  read-back no new write until the last one is read back from the device (power.limit within 1 W of what I wrote)
  enforced  the card obeys enforced.power.limit, which another authority (a lower board or system limit) can hold under
            the limit I request. The engine senses the enforced limit; each write is read back at once (requested,
            return code, power.limit, enforced limit, delay), and enforced under requested is recorded as an override.
            A driver without enforced.power.limit: power.limit is used and the snapshot says so.
  speed lock (--baseline-file, from tools/gpu_baseline.py on a run without Omni): the limit is set by response time
            alone. Over the last --lock-window-s of the response-time file, the mean, 95th and 99th percentile are each
            divided by the baseline's at the same arrival rate; the worst of the three is the speed ratio. The line is
            1 - --speed-gain (0.99: at least 1% faster than without Omni). Above the line: the start limit, at once.
            Under the line less --lock-margin: lower by --lock-step x start, times the slack in margins (up to
            --lock-boost), at most once per --lock-hold-s (the window must see the step before the next). Between: held
    . Never under --lock-floor x start.
            Speed won elsewhere (CPU conveyed to the serving pods, shorter queues) shows as a ratio under the line,
            and the lock spends it on watts; with nothing won elsewhere it holds the start limit.
  one writer the limit must be what I last wrote (or the start limit). Any other value means another writer: I stop
            writing for the rest of the run (observe only), record "foreign_writer", leave its limit alone on kill
            (restoring would fight it), and exit 5 so the bench marks the run invalid. Two controllers on one limit is
            how production is lost.
  heat      the device reporting a thermal or hardware slowdown (clock-limit reasons 0x8, 0x20, 0x40, 0x80): never
            tighten; the limit may only stay or rise (fail up).
  envelope  every decision records every rule that held the engine's request back ("blocked_by") and the one that
            decided ("decided_by": engine, a floor, the busy gate, a reflex, heat, or the speed lock), so a limit that
            did not move names its cause, and a result is credited to the rule that produced it.
  envelope  --floor-w, the buyer's declared lowest watts (the confirmation run requires it, scripts/gpu_paired.sh
  floor     ENVELOPE): the limit is never set under it. The highest watts are the limit read at start.
  outer     when the card's own controller (board, BMC or system policy) already holds enforced.power.limit under the
  holds     limit I set, a lower write that stays above that enforced value would change nothing the card does: it is
            not written ("outer_controller_holds"). Only a write that would actually bind, or a return upward, goes out
    .
Modes
  watch     everything above is computed and audited; nothing is written (the control arm)
  cap       the limit is written with nvidia-smi -i <gpu> -pl <W>. Refused at start unless every GPU reports
            power.management Enabled. A write the device refuses (nonzero return) ends the run: recorded, the start
            limit restored, exit 4, and the bench marks the arm invalid. No clock locks are ever written.
Kill switch
  the kill file (or SIGTERM) restores every GPU to the limit read at start, reads it back, and exits.
  The start limits are recorded first in the audit ("snapshot": power.limit, enforced.power.limit, default, min,
  max, persistence mode, power management, per GPU).

==== omni_controller/muscles.py (680 lines) ====
"""Live muscles for the Kubernetes controller beyond HPA and nodes.

Each muscle pulls (afferent) and pushes (efferent) through kubectl, records what it changed so the reset can hand
the muscle back, and tags every write with its muscle name in the audit log.

  power_cap   push: CPU limit of each running pod of the capped deployments = base limit x the governor's power cap,
              resized in place (no restart; Linux CFS quota throttles the containers for real); pull: power from --power-cmd
  heat        pull: thermal state from the harness heat law driven by live power stress (modelled: kind has no thermometer)
  security    pull: ConfigMap key "hold" == "true" means a security hold; the shield then blocks every expansion
  rollout     push: pause a deployment's rollout while the governor does not permit change; resume it when it does;
              undo a rollout that has exceeded its progress deadline when the governor authorises rollback
  batch       push: admit (unsuspend) held batch Jobs, one per decision, only when change is permitted and there is load
              and power headroom; running Jobs are never suspended
  latency     pull: 95th-percentile response time over the last --latency-window-s from --latency-file (CSV written by
              scripts/latency_probe.py); pressure max(0, p95 / --slo-ms - 1) enters the engine as queue pressure
  cpu_pstate  hardware connector. pull: --rapl-cmd prints package watts (e.g. from /sys/class/powercap/intel-rapl);
              push: --cpufreq-cmd with {khz}, the frequency ceiling = max frequency x power cap (e.g. writing
              scaling_max_freq with scripts/cpufreq_ceiling.sh {khz}, see hardware/SCHEDUTIL.md, or `cpupower frequency-set -u {khz}kHz`); kill runs it with the maximum frequency
  gpu         hardware connector. pull: --gpu-query-cmd prints "watts,celsius" (e.g. `nvidia-smi
              --query-gpu=power.draw,temperature.gpu --format=csv,noheader,nounits`); GPU temperature / --gpu-temp-limit
              feeds the heat sense; push: --gpu-power-cmd with {w}, the power limit = max limit x power cap
              (e.g. `nvidia-smi -pl {w}`); kill restores the maximum limit
  rightsize   push: each running pod's CPU *request* follows its measured use x (1 + headroom), resized in place through the
              pods/resize subresource (no restart); never above the limit, never below --rightsize-min-m; no decrease while
              the SLO is breached, no increase during a security hold; kill restores every original request
  coldstart   push: a deployment with no work waiting (ConfigMap key "queue" == 0, the queue a KEDA scaler would read) for
              --coldstart-idle decisions is scaled to zero; it is scaled back to its recorded replica count the moment
              work is waiting; kill restores the recorded count
  batch_pace  push: while power stress or heat is high, one running Job labelled omnicompass.io/pausable=true is suspended
              per decision (checkpointed training pauses instead of the site going over its limit); it is resumed when
              stress and heat are back down; kill resumes every Job Omni paused
  contain     push: an agent namespace whose measured CPU use exceeds --contain-cpu-m, or any namespace during a security
              hold, gets a ResourceQuota (limits.cpu = budget) and its running pods' CPU limits are scaled in place so the
              total fits the budget; lifted when use is back under budget; kill deletes the quota and restores the limits
  cooling     facility connector. push: --cooling-cmd with {c}, the supply-air setpoint moved between --cooling-min-c and
              --cooling-max-c by the heat state (warm setpoint while cool, saving chiller energy; cold setpoint as heat
              rises); kill runs it with --cooling-restore-c
  Hardware connectors are off unless their commands are given (not available on CI runners); the mechanism is the same.

        """Energy to where the work is (omnicompass/conveyance.py, on one machine's CPU).

        A serving pod's CPU limit is a quota: a request that needs more CPU than one quota period allows waits for the
        next period, while the machine it runs on sits idle. That wait is energy withheld from the work, not saved: the
        request uses the same CPU-seconds either way. So each machine's idle CPU is conveyed to the serving pods on it:

            c_i = min( max(L_i, (0.95 A_j - Q_j) / |P_j|), 0.95 A_j )

        A_j the machine's allocatable CPU, Q_j the requests of every other pod on it, P_j the serving pods on it, L_i the
        operator's own limit. The machine's last five percent is never handed out (the living band), a pod never gets
        less than its operator gave it, and the requests (what the scheduler and the autoscaler read) are untouched.
```

Confidential. Evaluation and simulation use only; any other use requires a signed, paid Omni-Compass Enterprise License.

```
        Resized in place through pods/resize: no pod restarts. No expansion during a security hold. The reset
        returns every pod to L_i.

        Conveyance is on by default. It moves no work: the same requests run with less waiting. (The +26% CPU seen on
        kind is more requests served, because that load is closed-loop, not waste.) Optionally, --convey-on (a share
        of --slo-ms) engages it only once the 95th-percentile response time reaches convey-on x SLO and releases it
        below convey-off x SLO, returning every serving pod to L_i; a blind latency sense engages it (service first).""

  4  """Replay a cluster capture (capture/kube_capture.sh schema) through the frozen fleet-mode governor in OBSERVE.
  5
  6  The recommended fleet is carried forward as the governor's own counterfactual state (the node count it would have
  7  reached), with load re-expressed against that fleet; the plant's response to the recommendation is not modelled.
  8  Outputs, per decision (every FLEET_DECISION_SECONDS): the observed node count and Omni-Compass's recommended node count
     ,
  9  power cap and HPA target, with the scheduling floor (never fewer nodes than running pod requests need). The summary
 10  compares observed node-hours with recommended node-hours and, if a node power model is supplied or power was captured,
 11  an estimated energy difference. All outputs are counterfactual recommendations; nothing is applied to the cluster.

==== fleet/harness.py (147 lines) ====

```
"""Fleet control-plane harness at 15-second resolution.

Plant: homogeneous node pools, workloads with CPU requests and actual usage, fluid request packing, per-workload
backlog, node boot delay (identical for every arm), power (idle + dynamic x utilization, scaled by power cap, PUE),
first-order thermal response, site power limit.

Execution layer (documented behaviour, not the upstream binaries):
  metrics-server   per-workload usage / request, published every 15 s from the previous tick (15 s lag)
  HPA              desired = ceil(current * metric / target); no change while |ratio - 1| <= 0.1; scale-up limited to
                   max(4 pods, 100%) per 15 s; scale-down uses the highest recommendation in the last 300 s
  ClusterAutoscaler  scan every 10 s (every tick here): add nodes for pending requests; remove one node when request
                   utilization < 0.5 for 10 min, not within 10 min of a scale-up
  Karpenter-lite   add exactly the nodes pending requests need; remove a node whenever the remaining nodes hold all
                   requests at <= 0.9 packing, checked every 30 s
Vessels:
  web        HPA-scaled services, diurnal load with bursts
  batch      job queue (no HPA): jobs request cores for a duration
  gpu        long training jobs on 8-GPU nodes, high power per node
  gpu_always_on  as gpu, but powering a node off is not permitted (training runs cannot be interrupted):
             controllers may only park idle nodes (Ready, drawing park_frac x idle power) and set power caps
  multi      four web clusters sharing one site power budget

"""Fleet simulation: arms x vessels at 15-second resolution.

Arms
  k8s_hpa60_ca, k8s_hpa70_ca, k8s_hpa80_ca   HPA at target 0.6 / 0.7 / 0.8 with Cluster Autoscaler
  k8s_hpa70_karpenter                        HPA 0.7 with Karpenter-lite
  omni_observe                               governor computes every minute, HPA 0.7 + CA act (must equal k8s_hpa70_ca)
  omni_target                                governor writes the HPA target (rho*) every minute; CA unchanged
  omni_fleet                                 governor is the single node and power authority (fleet-mode law, decisions
                                             every 60 s); HPA runs with target rho*; Cluster Autoscaler is not run;
                                             scheduling floor: never fewer nodes than current pod requests need;
                                             actions pass through the shield (I4 not applied)
  omni_fleet_balanced, omni_fleet_wear       omni_fleet with the equation (2) gate active in both directions
  omni_fleet_park                            omni_fleet (energy-first) with the idle-power path: capacity reductions park
                                             nodes (Ready, park_frac x idle power, wake in one tick) instead of powering
                                             them off; in pools where power-off is not permitted every arm parks
  omni_fleet_no_dynamics                     omni_fleet with equations (1)-(7) not evolved
  omni_fleet_no_gate                         omni_fleet without the equation (2) release gate
Batch and GPU vessels have no HPA; their omni_target arm equals the CA baseline and is omitted.
Every arm uses the same boot delay, plant, power model and scoring.

  4  """The compass law on every realm muscle (omnicompass/compass_law.py): each plant's knob held by its own compass.
  5
  6  Each plant's service is read as one position in its compass (0 calm, 1 the line): the worst of its queue or lateness, i
     ts
  7  load above half, and, for a storage site, its draw on the grid connection above half. The last period in violation
  8  reads as past the wall (fail up). The compass's force moves the knob: a positive force adds capacity, power, cooling or
  9  protection, a negative force gives it back, each knob inside its own cover. At the kill every knob returns to native.
 10
 11  Knob by plant (the override key the plant already obeys, its native value, its cover, and which way is "more"):
 12    compute_pool   power: limit share 0.4-1; replicas-type: the HPA target held at native (loosening it past the
 13                   operator's own costs the service time, the same rule as the card's speed floor); machine pools: one
 14                   machine released while the force is clearly down and the machines left cover the recent peak with
 15                   margin (RELEASE_MARGIN); admission: native
 16    thermal_zone   setpoint between the band's stress (colder, more cooling) and calm ends; units: one released while the
 17                   force is clearly down; power: native (a cooling cap moves heat later, never away)
 18    energy_storage reserve between the band's ends (a lower reserve gives the battery to the site); power: native
 19    motion_axis    speed and effort: 0.4-1
 20    process_loop   setpoint from native toward the band's calm end; actuator range 0.3-1; power 0.4-1
 21  """

  4  """A GPU card on its real physics, its own firmware, and the two-wire plug (evidence class S: a model, not a meter).
  5
  6  The card
  7    clock     f, a share of the top clock (1.0), moved by the firmware in bins of 0.9% (about 15 MHz on a 1.7 GHz part)
  8    power     P = idle + leakage(T) + P_dyn x busy x f x V(f)^2, with V(f) = 0.6 + 0.4 f: dynamic power rises with the
  9              clock and with the square of the voltage the clock needs, so the top of the clock range costs the most
 10    heat      C dT/dt = P - (T - T_amb) / R_th; leakage rises with temperature
 11    work      requests arrive (a slow wave, bursts, noise, drawn from the seed); the card serves f x mu per second;
 12              a request's response time is its wait plus its service time
 13
 14  The firmware (native, what ships on the card), 50 times a second
 15    boost     while there is work and room, raise the clock one bin, up to the clock ceiling
 16    hammer    while the draw is over the power limit, or the chip is over its slowdown temperature, drop three bins
 17    So the clock saws against the limit for as long as the work keeps coming: up a bin, knocked down three, up again.
 18
 19  The work
 20    memb      the share of a request's time at the top clock spent waiting on memory, which does not speed up with the
 21              clock: 0 is compute-bound work (large matrix products, the bench's pinned workload), 0.85 is typical of AI
 22              token generation (each token streams the model's weights from memory). The card serves 1 / ((1 - memb) / f
 23              + memb) of its top speed
 24
 25  The arms: each base alone, and the same base with Omni-Compass on top (Omni never runs the card itself)
 26    native    the card as shipped: power limit 150 W, clock ceiling at the top, firmware alone
 27    omni      native + Omni-Compass on top, through two wires (omnicompass/compass_law.py): the clock ceiling is the up w
    ire (how
 28              high boost may push), the power limit is the down wire (the lid, set just above what the ceiling draws,
 29              never under the card's own busy draw). The compass's reading is the response time as a position between the
 30              bare service time (0) and the service line (1); the brain pulls it to the center. The verdict
 31              (omnicompass/verdict.py) decides how far the ceiling may go: a step down is allowed only after a paired
 32              trial shows it costs each request at most ALLOW of the card's own time on it; where no step passes, the
 33              ceiling stays where the firmware has it. Both wires are restored to their snapshot at 90% of the run
 34    cap       a fixed power cap set by the operator and left (105 W, 70%), firmware alone under it
 35    cap_omni  the cap + Omni-Compass on top: the same law, the lid never above the operator's cap
 36  """

  4  """Realm harness: every muscle native, watched and governed; every realm, and the whole tower, as one organism.
  5
  6  Arms, all on the same seed (the same demand, weather, disturbances):
  7    native  the plant and its native controller alone
  8    watch   the frozen governor reads the plant every period and writes nothing; must equal native exactly
  9    omni    the frozen governor holds the muscle's one knob; at 90% of the run it is killed, the knob returns to the
 10            native controller, and the harness checks that it did
 11
 12  The governor is omnicompass.adapter.Governor, unchanged (the engine with u = 0, the stack law, the reset).
 13
 14  Single muscle: one plant, one governor reading that plant.
 15  Organism: all the plants of a realm (or all 656) on one 15 s clock, coupled: the electrical power of compute, motion
 16  and process plants is heat in the realm's thermal zones; the organism's load swing is load on its storage sites; the
 17  zones' temperature is the ambient every other plant reports. One governor reads the organism's aggregate and its one
 18  directive sets every muscle's knob.
 19
 20  Primary outcome per seed: work per energy, omni against native: (work_omni / work_native) / (energy_omni /
 21  energy_native) - 1. For an organism, work is the mean over its plants of work_omni / work_native (their work units
 22  differ) and energy is total joules. Guardrails: work not lower by more than 1%; the share of periods in violation not
 23  higher by more than 1 percentage point. Labels by rule (label()).

"""Realm plants: the machines the 656 muscles act on (evidence class S: declared models, not meters).

Five plant models. Each one carries its own native controller and runs correctly with no Omni at all:

  compute_pool    servers, nodes, GPUs, robots, radio cells or workers serving a request stream; native: the Kubernetes
                  HPA rule (desired = ceil(n * utilisation / target), 10% tolerance, scale-down stabilisation window,
                  start-up delay), a fixed admission limit, full clock
  thermal_zone    a data hall or building zone cooled by staged units; native: PI on a fixed setpoint, units staged to
                  the load, chiller COP from supply and outdoor temperature
  energy_storage  a site with load, solar and a battery behind a grid connection; native: self-consumption above a
                  fixed reserve
  motion_axis     a joint, flight axis, spacecraft axis or vehicle doing point-to-point moves from a task queue;
                  native: PID with feedforward at full speed, motor heating and derating
  process_loop    a first-order process with dead time (level, pressure, chamber temperature, feeder voltage);
                  native: PI on a fixed setpoint, pump or heater power from the actuator

A muscle is one knob of one plant. Omni may hold that knob and only that one; the native controller keeps the rest.
Omni commands a knob the way the shipped controller commands its organs (omni_controller/controller.py,
omni_controller/muscles.py), through the nervous system's authority (omnicompass/nervous_system.py, from_governor):

  expand     adding capacity, performance or protection is always allowed (except during a security hold)
  contract   giving any of it back (fewer machines, a lower speed or power limit, a warmer setpoint, a lower reserve
             of protection) only while the organ has contraction authority (calm >= the organ's threshold, senses live)
             and the plant's service has been clean for the last three decisions (the SLO reflex); continuous organs
             shed at most the calm fraction of their surplus per decision, discrete organs one unit, through a release
             gate (nothing waiting, and after the release the rest runs at or under the engine's utilisation target)
  fail up    while service is breached, the knob returns to the native controller at once
  pacing     admission muscles are batch pacing (the live batch_pace muscle): one muscle's work suspended per decision
             while power stress >= 0.95 or heat >= 0.96 or the nervous system calls a pause; one resumed per decision
             once power stress <= 0.8 and heat < 0.90 (realms/harness.py, pace)

By plant and knob:
  compute_pool  replicas and HPA-type knobs: the HPA target written as min(rho*, the operator's target), never tighter,
                held for one autoscaler window (the live controller's rule); machine pools (Cluster Autoscaler native):
                the node release gate; power: the GPU or CPU-frequency envelope, never under the work's draw plus 30%,
                and never on a request-served pool (the live controller: throttling it saves no energy, only adds
                wait); admission: batch pacing of pausable work only (request traffic is never paused)
  thermal_zone  setpoint: the live cooling law (warm while cool, cold as heat rises, inside [stress, stress + band x
                calm]); units: the release gate; power: the site power envelope above the load plus 10%; admission:
                paced, the migratable 10% is shed
  energy_storage reserve by power stress (released under stress, held when calm only with authority); peak-shave
                ceiling at rho* of the connection (expand only); battery power: the site power envelope; admission:
                paced, the flexible share is deferred; resumed, it is caught up
  motion_axis   speed: up at once to demand, down by the calm share of the surplus; effort: the power envelope;
                admission: paced, no new move starts
  process_loop  setpoint: toward the efficient end of its band by the calm share; actuator range: as motion speed;
                power: the site power envelope above use plus 10%; admission: paced, 10% is shed

Every disturbance trace is drawn from the seed when the plant is built, so all arms of a seed see the same ones.
Meters (work, energy_j, viol, steps) are kept by the plant from its own state; Omni never supplies them.

class K8sReference:
    """Documented-behaviour reference model of Kubernetes autoscaling (not the upstream controllers).

    HPA (kubernetes.io, Horizontal Pod Autoscaling): desired = ceil(current * metric / target); no change while
      |metric/target - 1| <= 0.1; scale-down uses the highest recommendation over the 300 s stabilization window.
      metric = load ratio; the target is workload configuration, so the benchmark runs targets 0.5, 0.6, 0.7, 0.8.
    Cluster Autoscaler (kubernetes/autoscaler FAQ), simplified: scale-up when work is unschedulable (backlog present),
      sized to the pending work, without scheduling-feasibility simulation; a node is removed after it has been unneede
d (utilization < 0.5) for 10 minutes, not within
      10 minutes of a scale-up.
    Alerting: page when queue ratio > 0.35 for 15 minutes (Prometheus 'for: 15m' rule).
    Terraform is not a live capacity controller (desired size ignored after creation).
    Power/thermal, rollout, rollback and routing proposals are executed as proposed.
    Not represented: Karpenter consolidation, VPA, pod scheduling constraints, disruption budgets.
    """

"""Work served under the closed-loop load (deploy/kind/loadgen.yaml), estimated per repetition.

  python3 tools/closed_loop_estimate.py DIR      # DIR holds bench-<arm>-<rep>/ with latency.csv, capture.csv, load_sch
edule.log

Each generator sends 20 requests one after another, each waiting for its answer, then sleeps RANDOM % 3 s (mean 1 s).
A generator's cycle is therefore 20 R + 1 s, R the mean response time, and it serves 20 / (20 R + 1) requests a second.
The requests of an arm are that rate times the generator-seconds of the load schedule. R is the mean response time of
the probe's successful requests in the same arm (the same service the generators call). The generators do not count
their requests, so this is an estimate; an open-loop load (LOADGEN=open) or a server-side count replaces it.
Prints, for Omni-Compass on top against native, paired over repetitions: requests, CPU used, CPU per request.
"""

  4  """The GPU test without a GPU: Omni-Compass's own GPU governor (omni_controller/gpu_governor.py, its command-line defau
     lts)
  5  against a modelled NVIDIA card, in virtual time. A preview, not evidence: every energy number here comes from the model
  6  below, not from a meter. The hardware answer is scripts/gpu_paired.sh on a real card.
  7
  8    python3 tools/gpu_physics_sim.py                     # 10 paired repetitions, both card models, table to stdout
  9    python3 tools/gpu_physics_sim.py --reps 5 --out results/gpu/sim --gov "--min-share 0 --util-gate 0"   # other setting
     s
 10
 11  The card (an assumption, stated):
 12    idle draw      40 W while no request is being served
 13    busy draw      P(s) = 80 + 220 s^gamma W at speed s (1 = full clock); 300 W at full clock, the start limit
 14    power limit L  below 300 W the card slows to the speed where P(s) = L, as real cards do by lowering clocks
 15    heat           first order toward 30 C + 0.12 C/W x draw, time constant 20 s
 16  gamma is how much the top of the clock range costs: 3 when voltage falls with clock (good for capping), 1.5 when the
 17  card already sits near its voltage floor (hard for capping). Both are run; a real card lies somewhere between.
 18
 19  The workload is tools/gpu_workload.py's: Poisson arrivals at 30, 60, 80, 30, 60, 30% of full-speed capacity, seed
 20  20260928 + repetition, one server first come first served, 50 ms per request at full speed, 600 s plus 30 s drain; the
 21  response-time target is ten service times (500 ms), as scripts/gpu_paired.sh sets it. The governor decides at its own
 22  interval (default 2 s) from the modelled card's nvidia-smi readings and the response-time file, exactly as on hardware.

  4  """Speed won on the CPU, spent on the GPU: a request served by a CPU stage and then a GPU stage, with Omni-Compass's
  5  speed lock (omni_controller/gpu_governor.py --baseline-file) on the GPU. A preview on a model, not evidence.
  6
  7    python3 tools/gpu_pipeline_sim.py                       # 10 paired repetitions, both card models
  8    python3 tools/gpu_pipeline_sim.py --cpu-ms 10 --out results/gpu/sim/pipeline
  9
 10  Each request needs --cpu-ms of CPU work on one core (preparing the input) and then the GPU (tools/gpu_physics_sim.py's
 11  card and workload: 50 ms at full clock, Poisson arrivals at 30/60/80/30/60/30% of GPU capacity). The serving pod's
 12  CPU limit is enforced as Linux does it (CFS bandwidth): a quota of limit x 100 ms of CPU time per 100 ms period; the
 13  pod's work runs at a full core until the period's quota is spent, then waits for the next period. The operator's
 14  --native-limit (0.5 core: 50 ms per 100 ms) throttles bursts; Omni's conveyance (omni_controller/muscles.py convey:
 15  the machine's idle CPU to the serving pods) raises the limit to --conveyed-limit (1 core: never throttled for one
 16  thread). Both stages are first come first served queues.
 17
 18  Arms, paired on the same arrivals:
 19    native  operator's CPU limit, GPU at its start limit (no Omni)
 20    speed   CPU conveyed, GPU at its start limit: the speed the CPU muscle wins, handed to the customer
 21    lock    CPU conveyed, GPU under the speed lock: the speed won is spent on GPU watts, keeping every gauge (mean,
 22            p95, p99) at least --speed-gain faster than native
 23  The lock's baseline comes from native runs on other seeds (tools/gpu_baseline.py), never from the arms judged.
 24  CPU work is the same core-seconds in every arm (conveyance moves no work, it removes waiting); only GPU energy differs.

  4  """The GPU bench table (scripts/gpu_paired.sh): native / watch (Omni runs, writes nothing) / omni (Omni writes power li
     mits).
  5
  6  Every energy number comes from the device: joules = the time integral of nvidia-smi power.draw over the measured window
  7  (trapezoid rule on its own sample timestamps), summed over the measured GPUs; the CPU package joules come from RAPL
  8  energy counters when the machine has them. Nothing here is a model.
  9
 10  Per repetition, per arm: energy, joules per served request, mean power, peak and mean temperature, served and not
 11  served requests, response time (mean, 95th, 99th percentile), power-limit writes. Across repetitions: for watch and omn
     i
 12  against native, the paired mean difference with a t-based 95% interval. A difference is proven when that interval
 13  excludes zero; otherwise the table says not proven.
 14
 15  Three contrasts, each paired by repetition: observation = watch − native (does Omni's presence alone move the plant),
 16  authority = omni − watch (what granting Omni the write adds), total = omni − native (the preregistered comparison).
 17  Three receipts, kept apart: A the governor's decisions (audit.jsonl), B its actuator records (requested, return code,
 18  read-back, enforced limit, delay), C the bench's own nvidia-smi samples and the workload's requests. From A and B the
 19  table also reports actuator fidelity, control effort, and how well the engine's six-state projection matches what the
 20  telemetry shows next (the intertwining residual and directional accuracy), defined in docs/GPU_PREREGISTRATION.md.
 21  The result label is chosen by rule (label()), never by hand. A meter that was not fitted prints UNAVAILABLE.
 22
 23  The run is INVALID (exit 2) when: a native or watch arm saw a power limit (or enforced limit) other than the one read a
     t
 24  start, the watch arm executed a write, an arm ended with a limit that differs from the start (the reset did not
 25  restore), a governor exited nonzero (a refused write, a refused start), a write was refused, Omni's frozen files
 26  changed, a confirmation ran on uncommitted code, or smoke and confirmation repetitions were mixed.
 27  Usage: python tools/gpu_reps.py RUN_DIR   (RUN_DIR holds rep-<n>/<arm>/)  ->  RUN_DIR/GPU_REPS.md, RUN_DIR/GPU_REPS.jso
     n"""

"""The wire check: before any test, prove both of the card's wires are connected the right way round.

Run as root on the machine with the card (scripts/gpu_rented_run.sh runs it first, and stops if it fails):

    sudo python3 tools/gpu_wire_check.py [--gpu 0] [--smi nvidia-smi]

  1 read        every meter answers: watts, temperature, utilization, power limit, clock, top clock
  2 snapshot    the starting power limit, read once
  3 up wire     with the card busy, read the clock it runs at on its own (its power limit may already hold it below
                the top), lock the ceiling at 60% of that: the clock must come down under it; reset it: the clock
                must come back above it (the ceiling is followed, in the right direction)
  4 down wire   set the power limit lower: the card must report it; set it back: the card must report the start
  5 restore     clocks reset and the start limit, read back
  6 stop        the two-wire governor, stopped by its stop signal, hands both wires back
  7 other writer someone else moves the limit while the governor runs: it must stop writing, leave that value alone and
                exit 5
Each step prints PASS or FAIL with the wire, the step and what the card said; the first failure stops the check (exit 1
)
and leaves the card at its start values. Exit 0: wired right.

"""The pinned GPU workload for scripts/gpu_paired.sh: a fixed stream of inference-like requests served by one GPU.

Each request is --iters passes of one of two kernels on the GPU (synchronised, so its time is the GPU's time):
  --kind matmul   fp16 matrix products of size --n x --n: compute-bound, its speed follows the core clock
  --kind decode   fp16 matrix times one vector, the weights --n x --n x --layers (by default 8192 x 8192 x 8, 1 GiB):
                  each pass streams every weight from the card's memory once, as AI token generation does at batch one,
                  so its speed follows the memory, not the core clock
Requests arrive open-loop on a schedule fixed by --seed: Poisson arrivals whose rate steps through --phases, each phase a
share of the GPU's own capacity measured by `calibrate` at full power before any arm runs. Every arm therefore receives
exactly the same requests at exactly the same moments; what differs is only how the GPU is governed.

  calibrate  times --calib requests back to back at the current (start) power limit and writes calib.json:
             iters (chosen so one request takes about --target-ms), service_ms, and every setting below
  run        serves the schedule for --duration seconds, then --drain seconds for requests still queued, and writes
             latency.csv  (elapsed_seconds, latency_ms, ok, service_ms)  live, one row per finished request; service_ms
                          is the card's own time on the request (start to done, the wait in the queue left out)
             requests.csv (arrival_s, start_s, done_s, latency_ms, ok)
             summary.json (requests, served, not served, t0_epoch: the wall clock at time 0, the settings)
Any other workload (vLLM, TensorRT-LLM, an MLPerf inference harness) plugs into the bench through WORKLOAD_CMD
(scripts/gpu_paired.sh) by writing the same three files; tools/gpu_reps.py checks them.
             A request still queued when the drain ends is not served (ok = 0).
--sim replaces the GPU by a sleep of service_ms (for the harness's own tests on machines without a GPU).

"""Real AI serving for the GPU bench: a language model served by vLLM (OpenAI-compatible server on this machine), asked
the same seeded stream of prompts in every arm, so the card's firmware alone and the firmware with Omni-Compass on top
get exactly the same requests at exactly the same moments.

Each request asks for exactly --tokens new tokens (ignore_eos), so every request is the same amount of work. It writes
the three files the bench reads (scripts/gpu_paired.sh, WORKLOAD_CMD):
  latency.csv   elapsed_seconds, latency_ms, ok, service_ms   one row per finished request (service_ms: the request's
                time in the server, which on a batching server is its time to finish)
  requests.csv  arrival_s, start_s, done_s, latency_ms, ok
  summary.json  requests, served, not served, t0_epoch, tokens per request, the model

  calibrate   time --calib requests one at a time; writes calib.json (service_ms: the median, the bench's response line
              is ten times it)
  run         serve the schedule for --duration seconds (Poisson arrivals at --rate per second), then --drain seconds

Tokens per second = requests served x --tokens / duration; the bench's work per energy is requests per kJ, so tokens
per kJ is that times --tokens.

"""The Omni index: one number for more for the same, or the same for less (docs/K8S_COMPASS_PREREGISTRATION.md).

Every measure of every test is turned into a ratio oriented so that above 1 is better for Omni-Compass:

  work      work with Omni / work native        (capacity, or requests served)
  speed     p95 native / p95 with Omni          (a lower response time is faster)
  machines  machines native / machines with Omni (in service, or billed machine-hours)
  energy    energy native / energy with Omni    (or the bill)

A test's index is the geometric mean of its ratios, minus one, in percent. A category is the geometric mean of its
tests; the headline is the geometric mean of the real categories, each weighted the same. The modelled muscles are
shown beside the headline, never inside it. Every number is read from the test's own result file (SOURCES below names
the file, the table and the row); nothing is typed in. A test that did not take a measure leaves it out.

"""The kill switch, from the command line (security: Omni-Compass off everywhere at once).
The master switch for the whole Omni-Compass harness (omnicompass/master.py).

  python3 tools/omni_switch.py off [--reason TEXT] [--wait 60]
      turns every Omni-Compass governor on this machine off at once: sets the switch, signals every running governor
      (SIGTERM), and waits until each has put every setting back and exited. Exit 0 when all are gone, 1 if any is
      still running after --wait seconds (its name and pid are printed; the switch stays OFF).
  python3 tools/omni_switch.py on
      allows governors to be started again (nothing restarts by itself)
  python3 tools/omni_switch.py status
      OFF or ON, every governor running, and any that died without handing back
  python3 tools/omni_switch.py watchdog [--stale 60] [--every 10] [--once]
      puts back every setting of any governor that died or hung without doing it itself (its recorded restore commands)
,
      stopping a hung one first; run it as its own service next to the governors

OMNI_MASTER_OFF sets the switch file (default /tmp/omni-compass/OFF); every governor and this tool must agree on it.

"""OmniCompass Runtime Benchmark Protocol (benchmark_protocol.docx), stage 1, on the fleet plant (fleet/sim_slo.py).

Same scenarios, same faults, every architecture:
  A  each platform alone        k8s_hpa70_ca, openshift, gke_optimize, aks_nap, turbonomic, cast_ai, spot_ocean
  B  Omni-Compass on top of it  omniB:<platform> with the frozen per-platform settings (tuning/B_SETTINGS_PER_PLATFORM.json)
  C  Omni-Compass alone         C-hpa: the held-out C league pick (HPA kept);  C-strict: the closure law, HPA replaced
                                (settings: tuning/CLOSURE_SEARCH2_DEV.json, else CLOSURE_SEARCH_DEV.json, else defaults)

Stress levels 1-5 (protocol section 6). Level L injects L fault events, times drawn uniformly in [120, 1200) ticks, each
one of (drawn with the seed, identical for every arm):
  node_crash      L x 10% of the cluster's running machines die at once (at least one)
  load_spike      every workload in the cluster: demand x (1 + 0.5 L) for 20-80 ticks        (queue overload, scaling)
  service_crash   L x 20% of the cluster's services lose half their pods (crash loop, restart churn) and queue
                  two ticks of demand as backlog
  cpu_pressure    a noisy neighbour: extra demand of L x 8% of the cluster's allocatable cores for 40-160 ticks,
                  spread over the workloads
Admissible basin, per tick (declared before any run): worst response time <= 1000 ms (10 x service time),
queue ratio < 0.28, pending pods <= 5% of requested, site power <= 1.02 x limit, thermal < 0.96.
Gauges (protocol section 7):
  conveyed          every fault recovered within 20 min (80 ticks) AND all clusters in the basin for the last 10 min
  recovery time     from a fault to the first tick that starts 2 min (8 ticks) in the basin; unrecovered = to the end
  failure persist.  minutes outside the basin
  pages             out-of-basin episodes lasting 5 min or longer (the Prometheus `for: 5m` rule): each one calls a
                    human (the protocol's human intervention count; nobody intervenes in the simulation)
  max error / CPU / queue / latency, timeouts (demand share with response > 2 s), work completed, energy
Usage: python tools/protocol_bench.py [runs_per_level=100]   ->  results/protocol/{raw_results.csv, summary_results.csv,
PROTOCOL_SUMMARY.json}

"""Build realms/catalog.csv: the 656-row muscle tower, each row given its realm, its plant, and the knob Omni may hold.

  python3 tools/realms_catalog.py CANONICAL_656_TOWER.csv

The tower itself (muscle id, family, name) comes unchanged from the XPASS package's canonical 656 list. This tool adds
four columns by the fixed rules below; the result is committed as data, so every row can be read and contested:

  realm     the muscle's home realm, by family
  realms    every realm whose organism includes it: its home realm, and all four for the shared spine (SPINE below):
            the infrastructure every real stack runs on (Kubernetes, machines, GPUs and CPUs, network, storage,
            observability, security, cooling, electrical distribution)
  template  the plant model the family runs on (realms/plants.py)
  preset    the family's parameter set for that plant (realms/presets.py)
  knob      the one knob Omni may hold for this muscle: capacity, setpoint, power or admission, from the muscle's name
            (first matching rule of its template, else capacity)

"""The release's one identity: RELEASE_MANIFEST.json.

  python3 tools/release_manifest.py           # write the manifest, run verify.py --quick, record its receipt
  python3 tools/release_manifest.py --check   # compare the files with the manifest (verify.py runs this)

The manifest names the commit it was written at and fingerprints (SHA-256) everything that identifies the release: the
canonical engine and the reference engine, the C++ twins (through the seal), the GPU protocol, the live evidence
(execution commit, run id and raw-file digests of sets 20 and 21), the canonical engine declaration, and the receipt
of the verification run made when it was written. One object, so nobody has to reconstruct provenance from history.

"""Omni-Compass on top of CityLearn's own controller: an independent, recognized simulator we did not write.

CityLearn (Intelligent Environments Lab, University of Texas at Austin; github.com/intelligent-environments-lab/citylearn,
MIT license) simulates districts of real buildings from measured data: each building's load, its solar panels, and its
battery, hour by hour for a year. It ships its own controllers. Its rule-based controller (citylearn.agents.rbc.BasicRBC)
is the native arm: it charges and discharges every battery by the hour of the day.

Arms, the same district, the same year, the same weather and loads:
  native  CityLearn's BasicRBC alone
  omni    the same BasicRBC, with the compass law (omnicompass/compass_law.py) on top of its electric battery commands only (a
          cold or hot water tank is a thermal muscle with its own reading and stays native). The reading is the
          district's draw without its batteries the hour before (the demand the batteries answer, not their own effect); its band is the 10th to the 90th percentile of the
          past week's draw (causal: only hours already seen). The compass's force moves every battery command the same way:
          a positive force (the district drawing hard) pushes toward discharge, a negative force (a quiet district)
          toward charge, by at most GAIN of the command's range, always inside the battery's own limits [-1, 1]. At
          KILL_AT of the year Omni-Compass hands every command back to the native controller, and the file checks it did

Scored by CityLearn's own evaluation (env.evaluate): every cost function as CityLearn defines it, each the controller's
value over the value with no battery at all (lower is better for every one: cost, electricity, carbon, peaks, ramping,
load factor). Nothing here is scored by Omni-Compass's own code.

  python3 tools/run_citylearn.py --datasets citylearn_challenge_2022_phase_all,... --out results/citylearn

"""The whole stacks with the real card inside: one harness, one engine, one set of receipts.

Each of six organisms (the four realms, the four stacked with every duplicate kept, 1,226, and the whole tower of 656,
realms/catalog.csv) runs on one clock as in the realm
harness, and the real GPU on this machine is wired into it as one more muscle of its NVIDIA GPU family (a spine family,
so the card sits in every organism): the card serves the pinned request stream (tools/gpu_workload.py), its own
power.draw is heat in the organism's thermal zones and load on its storage sites, and its meter and its requests are
counted in the organism's receipt.

Arms, the same organism, the same seed, the same request stream:
  native  the stacks' own controllers and the card's own firmware, no Omni
  omni    one engine on everything: the compass law (omnicompass/compass_law.py) on every simulated muscle (realms/comp
ass_arm.py)
          and on the card's two wires (omni_controller/gpu_compass.py); at 90% of the arm every knob and both wires are
          handed back, and the harness checks they were

Sizes (--scales, default 1,10,100,1000): each organism is run as 1, 10, 100 and 1,000 copies governed together on one
clock (1,000 copies of the whole tower is 656,000 muscles), with the one real card inside as one more muscle. Each size
runs its own number of paired repetitions (--reps-by-scale, default 5,3,2,1; amendment 11 of docs/GPU_PREREGISTRATION.m
d).

Each organism step is --step-s seconds of wall clock (240 steps: 8 minutes at 2 s). A size whose simulated step takes
longer than that gets a longer step, measured on this machine before the run (1.5 times the time the simulation needs
per muscle, times its muscles); the card's request stream runs for the same 240 steps, so the card and the stacks stay
on one clock. Every size's step is in the receipt. The simulated plants are evidence class S (models); the card's
energy and requests are class P (its own meter). The receipt keeps them apart and also adds them up.

  python3 tools/run_hil.py --out results/hil/run-STAMP [--scales 1,10,100,1000] [--reps-by-scale 5,3,2,1] [--sim]
  python3 tools/run_hil.py --rescore results/hil/run-STAMP      (a finished run reported in full from its own files)

"""The whole stacks with the real Kubernetes cluster inside: one organism, one clock, one engine.

Started by scripts/kind_bench.sh when ORGANISM is set (kind on GitHub, or AKS on Azure). One of the six organisms of
tools/run_hil.py (the four realms, the four stacked with every duplicate kept, 1,226, and the whole tower of 656) runs
on the measured window's clock, ORGANISM_STEPS steps, and the real cluster is wired into it as one more muscle:

  efferent  the organism's own compute demand drives the cluster. Demand at step k is the organism's offered work
            over its declared mean (sum over its compute pools of lam[k] / lam0, the seeded trace, the same in both
            arms). The load generator runs 1 + round((LOAD_MAX - 1) * (demand[k] - least) / (most - least))
            replicas: the organism's quietest step is one generator, its peak is LOAD_MAX, so the cluster serves the
            organism's own swings across the whole declared range.
  afferent  the cluster's watts (capture.csv, the declared power model, the same in both arms) are heat in the
            organism's thermal zones and load on its storage sites, as the card's watts are in tools/run_hil.py.

Arms, the same organism, the same seed, the same demand:
  native  the stacks' own controllers, and Kubernetes alone underneath (Omni-Compass not started)
  omni / compass  one engine on everything: the compass law (omnicompass/compass_law.py) on every simulated muscle
          (realms/compass_arm.py) and the live controller on the cluster (started by kind_bench.sh). At KILL_AT of the
          window every simulated knob is handed back, and this file checks it was.

Writes organism.json (every plant's receipt, the steps, the replica trace, the cluster's watts as the organism saw
them) and appends each replica change to load_schedule.log in the format scripts/kind_bench.sh writes.

Sizes (--scale): 1, 10, 100 or 1,000 copies of the organism governed together on one clock (as tools/run_hil.py), the
one real cluster inside. A large organism is built before the window opens: this file writes organism.ready when it is
built and starts on the epoch written to the go file (--go-file), so the cluster's window and the organism's clock open
together however long the build takes.

  python3 tools/run_kil.py --organism organism_656 --arm compass --duration 960 --out DIR [--scale 10] [--go-file F]

"""Omni-Compass on top of a distribution grid's own voltage control, in pandapower (docs/PANDAPOWER_PREREGISTRATION.md)
.

An independent, recognized simulator and data set: pandapower (Fraunhofer IEE and the University of Kassel; BSD) solves
the AC power flow; SimBench (the German benchmark grids, with a year of 15-minute load, solar and wind profiles) gives
the grids and their year. Both are someone else's work; nothing here models the grid.

  native  the substation's on-load tap changer holds the medium-voltage busbar at its setpoint (1.00 per unit) inside a
          deadband of half a tap step, one tap per step at most; solar and wind at unity power factor (as SimBench has
          them). This is how a utility runs it on its own.
  omni    the same tap changer, with the compass law (omnicompass/compass_law.py) on top of its setpoint: it reads the
          worst voltage margin anywhere in the grid (the bus nearest either limit, 0.95 and 1.05 per unit) and moves th
e
          setpoint inside [0.97, 1.03]: down while every bus has room (conservation voltage reduction), away from the
          nearer limit as soon as one bus nears it, and straight back to native at a violation. At KILL_AT of the year
          the setpoint is handed back. Every move is one whole tap; a move toward saving needs a full week seen under t
he
          present setpoint whose worst moment still leaves every bus MARGIN after one more tap; a move away from a limi
t
          is at once, once the utility's tap changer has reached the present setpoint.

Scored by pandapower itself, the same grid and the same year in both arms:
  energy drawn from the upstream grid (MWh), line and transformer losses (MWh), bus-hours outside [0.95, 1.05],
  tap operations (wear), and the lowest and highest voltage seen.

Loads: SimBench's loads are constant power. Lowering the voltage saves energy only where a load draws less at a lower
voltage, so the run is made twice: with a declared ZIP mix (40% constant impedance, 30% constant current, 30% constant
power, a common residential mix) and with SimBench's own constant-power loads, where only losses can change.

  python3 tools/run_pandapower.py --grids 1-MV-rural--0-sw --out out [--step 4]   (step 4: hourly, every 4th quarter ho
ur)
  python3 tools/run_pandapower.py --report-only DIR --out DIR

"""The six organisms with the real cluster inside: twelve columns, one report.

Reads every bench-<arm>-<rep>/ under DIR that carries organism.json (tools/run_kil.py, started by scripts/kind_bench.sh
with ORGANISM set), groups the runs by organism, and pairs each Omni arm with native by repetition. Each organism gives
two columns, native and native with Omni-Compass on top: six organisms, twelve columns.

Two kinds of rows, kept apart:
  the cluster  real Kubernetes, measured (response times from the probe, pods, replicas and CPU from the API server;
               energy from the declared power model; on AKS the bill from Azure's own count of machines)
  the organism the simulated stacks around it (evidence S, models): work, energy, time over the line

Each organism's line names what came out better and what came out worse than native, by any amount, and which of
those are inside the noise (the interval crosses zero). CPU and host load are shown, not judged. No line is drawn.

"""Whole-machine watts from the wall, read from a smart plug that Omni-Compass never reads or writes.

The plug sits between the wall socket and the machine under test. Its reading covers everything the machine draws:
GPU, CPU, memory, fans, power-supply losses. It is the measurement a buyer understands at once, and it is independent
of Omni by construction: the governor is never given the plug's address.

SPEC
  shelly1:<ip>      Shelly Gen1 plug (Plug S, Plug US):  http://<ip>/meter/0            -> "power"
  shelly2:<ip>      Shelly Gen2/Gen3 plug (Plus Plug):   http://<ip>/rpc/Switch.GetStatus?id=0 -> "apower"
  tasmota:<ip>      any plug flashed with Tasmota:       http://<ip>/cm?cmnd=Status%208 -> StatusSNS.ENERGY.Power
  ipmi:local        the server's own management controller, read on the machine: ipmitool dcmi power reading
  ipmi:<host>       the same over the network (IPMI_USER, IPMI_PASSWORD): ipmitool -I lanplus -H <host> ...
  redfish:<host>    the management controller over Redfish (REDFISH_USER, REDFISH_PASSWORD): the first chassis's
                    PowerControl PowerConsumedWatts, or its EnvironmentMetrics PowerWatts on newer controllers. The
                    controller's certificate is checked against REDFISH_CA (a file); REDFISH_INSECURE=1 skips the
                    check for a controller with a self-signed certificate on a private management network
  cmd:<command>     any shell command that prints watts (a USB meter, a PDU script, a lab instrument)
Usage
  python tools/wall_meter.py SPEC --once              print one reading (check the plug before a run)
  python tools/wall_meter.py SPEC OUT.csv [--interval 1]   write epoch_s,watts until stopped

# The 8-GPU result, one command on a rented machine with several NVIDIA cards (docs/GPU_RUN_GUIDE.md, section D):
#
#   sudo bash scripts/gpu_8card.sh            the whole design, about 17 to 18 hours
#   sudo POOLED=1 bash scripts/gpu_8card.sh   every stage, repetitions pooled across the cards, about 9 to 10 hours
#   sudo FAST=1 bash scripts/gpu_8card.sh     the short design, about 3.5 hours (what only a full server shows)
#
# Every card on the machine runs the whole card test at the same time (scripts/gpu_rented_run.sh with GPU=<card>): its
# own wire check, envelope, smoke, the two preregistered confirmations (compute and AI token generation) and the
# operator's power cap underneath, each card its own firmware alone against the firmware with Omni-Compass on top, on
# the same committed code. The cards share one machine, its power supply, its cooling and its neighbours' heat, as in a
# real server. Each card starts its arm rotation one step later than the card before it, so at any moment some cards
# run native and some run Omni-Compass, and no arm always meets the same neighbours.
# Then, with every card idle again: the GPU fault drill once, on card 0 (the master switch stops every governor on the
# machine, so it never runs while the cards measure). Then one pooled table per workload: every repetition of every
# card, paired within its own card (tools/gpu_reps.py), and each card's own table beside it.
#
# Last, the whole server as one: a language model served across every card at once (scripts/gpu_vllm.sh with GPU=all
# cards: vLLM tensor parallel, one Omni-Compass governor per card, the server's total GPU energy), SKIP_LLM=1 skips it.
# Then the whole stacks with a real card inside: the six organisms at 1x, 10x, 100x and 1,000x copies, full
# repetitions, each organism on its own card at the same time (SKIP_HIL=1 skips it; HIL_ARGS passes options through).
# CARDS (default: every card nvidia-smi lists), SKIP_DECODE=1, SKIP_CAP=1, SKIP_DRILL=1 as in gpu_rented_run.sh.

# One command on a machine with an NVIDIA GPU: native vs Omni-Compass watching vs Omni-Compass governing the GPU's
# power limit, measured by the device itself. Run as root (nvidia-smi -pl needs it). Needs python3 with torch (CUDA).
#
#   sudo bash scripts/gpu_paired.sh                 # 5 repetitions x 3 arms x 10 min (about 3 hours with idle gaps)
#   sudo REPS=5 DURATION=300 bash scripts/gpu_paired.sh   # shorter arms
#
# Each repetition runs the three arms back to back, order rotated. Each arm: COOLDOWN s idle, then the pinned workload
# (tools/gpu_workload.py: the same seeded stream of fp16 matrix-product requests every arm) for DURATION s plus DRAIN s
,
# with nvidia-smi sampling power.draw, temperature and power.limit every SAMPLE_MS ms, and RAPL CPU package energy
# counters read at both ends where the machine has them.
#   native  no Omni process
#   watch   Omni runs and decides, and is forbidden to write (the control: any write fails the run)
#   omni    Omni holds the card's two wires, clock ceiling and power limit (omni_controller/gpu_compass.py --mode cap;
#           OMNI_ENGINE=one_wire runs the earlier power-limit-only governor, omni_controller/gpu_governor.py)
# Three receipts, kept apart: A the governor's audit.jsonl (telemetry, six-state reading, command, shield), B its
# actuator records (requested, return code, read-back, enforced limit, delay), C the bench's own nvidia-smi sampling
# and the workload's requests.csv (Omni never supplies its own outcome). Refused unless power management is Enabled.
# The power limit is read once at the start (the snapshot). Every arm must begin and end at it; the reset restores
# it after the omni arm. The table (tools/gpu_reps.py) prints each gauge with its 95% interval; an interval that includ
es
# zero says not proven. Output: results/gpu/run-<UTC time>/ with every raw file and SHA256SUMS.txt.

# The whole GPU test on a rented NVIDIA machine, one command (docs/GPU_RUN_GUIDE.md, section C):
#
#   sudo bash scripts/gpu_rented_run.sh
#
# 1. checks the machine (NVIDIA GPU, root, PyTorch with CUDA, power management Enabled), then the wire check
#    (tools/gpu_wire_check.py: both of the card's wires follow, read back and go home);
# 2. declares the envelope before any trial (docs/GPU_PREREGISTRATION.md, amendment 3): lowest watts =
#    max(device minimum, 70% of the limit read now), unless ENVELOPE=file.json is given;
# 3. smoke: 3 repetitions x 3 arms x 180 s (about 40 minutes). It checks the wiring on real hardware. It never counts;
# 4. if smoke is valid: the preregistered confirmation, 10 repetitions x 3 arms x 600 s (about 6 hours), on the same
#    committed code (STOP_AFTER_SMOKE=1 stops after step 3), on the pinned compute-bound workload (matrix products);
# 5. the second preregistered confirmation, the same 10 x 3 x 600 s on AI token generation (the decode workload:
#    every weight streamed from memory once per pass, batch one), about 6 hours more (SKIP_DECODE=1 skips it). Each
#    workload is its own result, never pooled;
# 6. an operator's power cap underneath (70% of the default limit): the cap alone vs the cap with Omni-Compass on top,
#    at the usual load and fully loaded (more work from the same watts), 5 repetitions each, 300 s per arm, about 3 hou
rs
#    (SKIP_CAP=1);
# 7. the GPU fault drill, about 10 minutes: the governor killed outright, the master switch pulled, the response feed
#    blind (SKIP_DRILL=1); everything so far is then packed;
# 8. the whole stacks with this card inside (tools/run_hil.py): the four realms, the four stacked with duplicates
#    (1,226) and the whole tower (656), each as 1, 10, 100 and 1,000 copies on one clock with the card inside, native
#    and Omni (repetitions 3, 3, 2, 1 by size; HIL_SCALES and HIL_REPS_BY_SCALE change them; SKIP_HIL=1 skips it);
# 9. real AI serving last: a language model served by vLLM, installed in its own environment, 5 repetitions x 3 arms x
#    300 s; if it cannot install or start, the stage says so and nothing before it is affected (SKIP_LLM=1);
# 10. packs every result folder into one file to send back, and prints the label each table chose by rule.

# One arm of the native-vs-Omni benchmark on the six-worker kind cluster (deploy/kind/cluster-full.yaml).
# Both arms are wired identically: same cluster, add-ons, workload, HPA (target 50), load schedule, capture and
# power model. The only difference:
#   ARM=native  Omni-Compass is not started at all. Kubernetes (HPA, scheduler) runs alone on all workers.
#   ARM=omni    Omni-Compass runs in nodepool mode with every live muscle: HPA target, node pool (prefer-not idle mark, first-to-go order),
#               power cap (CPU limit of php-apache, enforced by the kernel), heat (harness law on live power), security
#               (ConfigMap hold), rollout guard, and the latency afferent: 95th-percentile response time over SLO_MS
#               (declared before the run, default 500 ms) enters the engine as queue pressure. The power cap never goes
#               below pod usage x 1.3. Parked workers stay powered and Ready at their idle floor (STANDBY_W =
#               park_frac x idle, never off).
#   ARM=watch   Omni-Compass runs exactly as in ARM=omni (same process, same reads, same senses, same decisions) with
#               --dry-run: every write is logged, none is executed. Any difference from native in this arm is the cost of
#               Omni-Compass being there (its CPU on the shared runner, its API reads) plus run-to-run noise, never a
#               decision. The run fails if one write reached the cluster.
# The controller runs at the lowest CPU priority (nice 19) in every Omni arm: on a real cluster it runs on its own node,
# here all seven kind nodes share one 4-core runner with the service being measured.
# Both arms: a real response-time probe times HTTP requests to php-apache every 5 s (latency.csv).
# Load schedule: the load-generator replica count steps through LOAD_STEPS, each step DURATION/steps seconds,
# identical in both arms. Results in $OUT_DIR: capture.csv (every 15 s), nodes timeline, Omni audit (omni arm).
# Evidence discipline (adopted from the ChatGPT-built harness, extended to every muscle): pinned, SHA-256-checked
# metrics-server; preflight record of tool versions; clean-cluster check; Omni-Compass runs as a least-privilege service
# account (deploy/kind/rbac-omni.yaml) with `kubectl auth can-i` receipts for what it can and cannot do; the run fails if
# Omni made no write or if the reset leaves any record behind; SHA256SUMS.txt fingerprints every output file.

# Live proof of the added levers on a real Kubernetes API server (kind): rightsize, coldstart, batch pace, containment
# and the cooling connector. Omni-Compass runs as its least-privilege service account (rbac-omni.yaml + rbac-levers.yaml,
# with `kubectl auth can-i` receipts). For each lever the script drives the triggering condition, checks with kubectl that
# the real object changed, then fires the reset from a fresh process and checks every object is back and no
# omnicompass.io record is left. The cooling connector writes to a stand-in building controller (a file): a CI runner has
# no chiller, so that lever proves the mechanism only. Results in $OUT_DIR/levers.txt.

# Node-pool actuator: keep exactly N worker nodes in service; the others idle, never powered off, and no pod is ever
# moved, evicted or restarted to make that happen.
# Idle a worker: mark it omnicompass.io/idle:PreferNoSchedule (new pods go to open workers first, but a pod that finds
# them full lands here at once, so no pod ever waits because of me) and mark its pods first to go
# (controller.kubernetes.io/pod-deletion-cost), so the autoscaler's own scale-down removes them as the load falls. A
# closed worker still carrying work is in service; once its work is gone it idles, powered and Ready at its floor.
# Wake a worker: remove the mark (those still carrying work first, they are warm), clear the marks on its pods; it is i
n
# service at once, with no boot.
# Which workers idle: fewest serving pods first, then fewest pods, so an empty worker idles before one with work.

# Omni-Compass on a real Kubernetes control plane at scale: a kind cluster whose worker nodes are KWOK nodes (the
# Kubernetes project's own tool: real Node and Pod objects in the real API server, no machines behind them).
#
#   NODES=500 bash scripts/kwok_scale.sh
#
# It builds NODES worker nodes (4 CPU each), NODES/10 Deployments with their HPAs (CPU target 50) and two pods per node
,
# then runs the controller (compass law, HPA target and node pool, the verdict) for ITER decisions against a response-t
ime
# feed that is calm, then hot, then calm. It measures what the controller costs at that size (decision time, its own
# CPU) and checks that its counts are right and its commands land; then the master switch turns the whole harness off,
# and every HPA target and every node must be back as the operator had them. Writes $OUT/KWOK.json.

  4  # Serving path for the live benchmark (applied in BOTH arms by scripts/kind_bench.sh).
  5  # 1. A NodePort in front of php-apache. The response-time probe reaches the app the way a client does: through the
  6  #    Service, via kube-proxy on the control-plane node (never parked), load-balanced across every ready endpoint.
  7  #    A tunnel to one pod (kubectl port-forward) would hang when a drain moves that pod and count every later request as
  8  #    failed in the draining arm only; the Service path measures what a real client sees.
  9  # 2. A PodDisruptionBudget, the standard Kubernetes guard for voluntary disruption: a drain may never evict the last
 10  #    ready replica. Kubernetes alone never evicts in this benchmark, so the budget binds only when nodes are drained.

"""Energy to where the work is, against the fake kubectl: each machine's idle CPU (inside the living band, less the
requests of every other pod on it) is conveyed to the serving pods on it as their CPU limit, resized in place with no
restart and never below the operator's limit; requests are untouched; a security hold blocks expansion; a machine
crowded with other work leaves the operator's limit as it is; the reset returns every pod to the operator's
limit. A machine closed to new work that still carries work keeps counting in service, and my machine orders are
judged by the machines open to work."""

  4  """CPU-frequency lever through the kernel's policy files (hardware/cpufreq.py, contract adopted from the ChatGPT
  5  release, wired here under the nervous system). On a fake sysfs tree:
  6    C1 schedutil map: request = min(1, 1.25 u), tipping at u = 0.8
  7    C2 a ceiling never exceeds the operator's pre-Omni ceiling and never crosses scaling_min_freq
  8    C3 exact restore of every policy's pre-Omni ceiling (not the silicon maximum)
  9    C4 governor gate: refuses non-schedutil policies when required
 10    C5 the lever never sets a ceiling below the schedutil request at the current utilisation (no performance cut)
 11    C6 the lever stays inside the nervous-system envelope; the heat ceiling wins over the schedutil floor
 12    C7 reset restores the exact values, with an audit record"""

"""The GPU bench (scripts/gpu_paired.sh, omni_controller/gpu_governor.py, tools/gpu_reps.py) against a stand-in nvidia-
smi
(tests/fake_gpu/nvidia-smi): the governor's contract and the bench's validity checks, without a GPU.

Governor contract: the start limit is read and recorded before any write; watch computes and records but executes no
write; a written limit is never below draw x 1.3 nor the device minimum, never above the start limit; no second write
until the last one reads back; a blind sense returns the start limit; a response-time breach returns the start limit;
the reset restores the start limit and reads it back.
Bench: one command runs native / watch / omni with rotated order and prints the table; a watch arm that writes, or an
arm that ends away from the start limit, makes the run INVALID."""

"""The master switch (omnicompass/master.py, tools/omni_switch.py): one OFF for the whole harness.

Two governors run at once as their own processes, against the stand-in hardware: the two-wire GPU governor on the fake
nvidia-smi, and the Kubernetes controller (compass law, HPA target mode) on the fake kubectl. Then:

  running   both register themselves; status lists both
  off       one command turns the whole harness off: both governors put every setting back (the card's start limit and
            clocks, the operator's HPA target) and exit, within seconds
  refused   while the switch is OFF, neither governor will start (no authority taken)
  on        after ON, a governor starts again
  crash     both governors killed outright (SIGKILL: no chance to hand back) while acting; status names them; the
            watchdog runs their recorded restore commands: the HPA target back to the operator's and the card's clocks
            and limit back to the start

"""Two-way nervous system (manuscript Appendix J: the nervous system owns sensing integrity, delay and dropout handling
,
and feedback interpretation).
W1 afferent integrity: a blind sense (stale > 0) never grants any organ contraction and never admits held batch work,
   over random engine states; capacity expansion is untouched (the safe direction), and pausing batch (its protective
   contraction) stays allowed
W2 the latency sense is judged against the wall clock: a frozen probe file is blind even if its last window was clean
   (a hung probe must never be read as the present); a window with no successful request is blind; a fresh clean window
 is live
W3 failed requests in a live window become latency pressure (a failure is never read as silence)
W4 efferent feedback: the node gate refuses a new release while a sense is blind or the last node command did not land"

PREFACE = """I wrote this book so that whoever connects Omni-Compass to a running system understands what they are
connecting: not only which wire goes where, but why the governor behaves the way it does, where its law comes from,
and how to prove on their own system what it does for them.

The book is in eight parts, and it can be read in two ways.

| You are | Read |
|---|---|
| CEO, board member, investor | the Foreword, the Executive Summary, Part One, the Results to Date, and Part Eight |
| CTO, architect, head of platform | Parts One to Four, then the eight wiring levels in Part Five, then Part Seven |
| The engineer wiring it | everything, in order. Do not skip the wire check or the watch level |
| Auditor, diligence team | Part Two (the mathematics), Part Seven (the proof), Appendices C, F and H |

**Part One, the philosophy and the theory,** sets out the closed circle: a system that is closed, bounded and pulled
toward a center cannot run away, and everything it does is a return. **Part Two, the mathematics,** gives the eight
equations and the control law that make the circle exact, with the theorem, the declaration and the audits that hold
them fixed. **Part Three, the physics,** brings the law into the machine: the compass, push and pull, the band and its
cushions, the physics of a processor, and the two-way nervous system. **Part Four, the body,** lays out the 656
muscles, the four realms and the six organisms. **Part Five, the harness and the wiring,** is the universal plug and
the step-by-step work of wiring Omni-Compass onto a stack. **Part Six, operating it,** is the OFF switch, the rules
and the log. **Part Seven, proving it,** is every rule written before a run and every result after it. **Part Eight**
is value, the license, the seal and the history.

**Conventions.** `Code` is a command, file or switch exactly as typed. "Native" means a system as it runs today,
without Omni-Compass. "Muscle" means any machine, service or controller Omni-Compass can read and set. "Knob" or
"lever" is one setting on a muscle. "The band" is a knob's or a service reading's safe range. A step that writes to a
system is marked **WRITES**. Every result carries its evidence class: T for a theorem, V for verification of the code,
S for simulation, L for live software, P for a physical meter.

Some chapters gather documents that were written as the work went on, each at the moment its result came in. They
are kept as they were written, because the record of how a result was reached is part of the proof. Where two
chapters give different figures for the same thing, the later run and the State of Play govern."""

dd = f"""# Due Diligence

Answers reference the Claims Register (C-numbers) and the Technical Manual.

## Engineering
**Does the mathematics hold?** Equations (1) to (8), Propositions 1 to 3 and their proofs are in Manual Chapters 2 and
3. The 500/500 CONVEY/CERT result is a property of the controller (Proposition 3), shown by counterfactuals: the contro
ller aimed at the wrong basin also scores {CORE['wrong_target']['convey5']}/500.
**Is Python the same as C++?** Yes (C1, C2). The verifier also builds a deliberately mutated C++ governor and confirms
the parity test rejects it.
**Can every number be reproduced?** `python verify.py` rebuilds the C++, reruns parity, reruns the 100,000,000-decision
 soak and compares it with the recorded result, replays held-out scenarios and checks the pre-registered SHA-256 hashes
 (program fingerprints are additionally checked when the Python version matches the recorded one).

## Operations
**Better than what we run today?** Compared against a documented-behaviour reference model of Kubernetes autoscaling (H
PA tolerance 0.1, 300 s scale-down stabilization, HPA targets 0.5 to 0.8; simplified Cluster Autoscaler with 10-minute
unneeded time, 0.5 utilization threshold, 10-minute delay after scale-up): C8 to C12, including where Omni-Compass is w
orse. The reference model is not the upstream controllers (C12b); running the upstream controllers against the same sce
narios is the next baseline step.
**On real traffic?** Not yet. Results use a synthetic stack model. Replay of published production traces and the pilot
protocol are the next evidence steps (C14).
**What happens when it is wrong?** Observe mode changes nothing (C6). The reset returns control to the native managers
at the next interval (omni_kill arm). The shield blocks actions that violate I1 to I5 (C7).
**Will it wear hardware?** Machine start/stop cycles, power-cap travel and thermal travel are measured for every arm (C
12, Manual Chapter 8).

## Security
**What authority does it hold?** Capacity, replicas, power caps, rollback authorization and routing, only in AUTOPILOT,
 only through the shield.
```

Confidential. Evaluation and simulation use only; any other use requires a signed, paid Omni-Compass Enterprise License.

```
**Can it expand capacity during a security block?** No: invariant I1 is enforced before execution.
**Does it replace encryption, identity or policy engines?** No. Those components are retained (fleet model, security role).

## Finance
**What does it save?** Energy per run versus current autoscaling (C8). Fleet-scale figures are modeled (C13); the governance saving comes from reduced idle and padded capacity, not from removing the decision components' own consumption.
**What does it cost to run?** C5.

## Adoption
**How is it introduced without risk?** Observe, then shadow on production telemetry, then one control loop at a time under the reset (docs/PILOT_PROTOCOL.md).

## Referees
**Was it tuned on the test data?** No. Law, shield and baselines were frozen and fingerprinted before the held-out seeds {S1} and {S2} (results/PREREGISTRATION.json).
**Where does it fail?** Backlog violations against current autoscaling (C11); the engine-dynamics ablation (Manual Chapter 8); open obligations (Manual Chapter 10).
"""
(ROOT / "docs" / "DUE_DILIGENCE.md").write_text(dd)

pp = """# Pilot Protocol

## Phase 0: Simulation evaluation (evaluator's own environment)
Run `python verify.py`. Pass criterion: VERIFICATION: PASS.

## Phase 1: Shadow (2 to 4 weeks)
- Capture: `OUT=capture.csv INTERVAL=15 DURATION=<seconds> POWER_CMD="<site power in watts>" bash fleet/capture/kube_capture.sh` (read-only).
- Replay: `python fleet/capture_replay.py capture.csv --idle-w <W> --dyn-w <W> --site-limit-w <W> --out replay/` gives Omni-Compass's recommended node count, power cap and HPA target per decision.
- Governor in OBSERVE on production telemetry read directly from nodes (kubelet/cAdvisor metrics, power meters, queue depth).
- No write credentials are issued.
- Logged per interval: directive, native actions taken, and the observed outcome.
- Pass criteria, agreed before start: logged directives never violate I1 to I5; counterfactual analysis on at least N recorded incidents shows the directive would have reduced time-to-recovery or energy without a backlog increase beyond an agreed bound.

## Phase 2: Guarded control, one loop at a time (4 to 8 weeks)
Order: power capping; node count (Cluster Autoscaler set to observe); replica count (HPA set to observe).
- Each loop is handed over separately, with the reset tested at handover and at exit.
- Pass criteria per loop, fixed in advance: SLO attainment not worse than the preceding shadow baseline at the agreed confidence level; zero shield invariant violations; energy per unit of completed work reported with confidence intervals.
- Exit: any criterion failed triggers the reset and returns the loop to its native controller.

## Scoring your own pilot
Capture the baseline (a period before the controller, or a matched node pool left on your normal autoscaler) and the
Omni-Compass period or pool with fleet/capture/kube_capture.sh, then:
`python pilot/score.py --baseline baseline.csv --omni omni.csv [--idle-w W --dyn-w W]`
It reports node-hours and energy per used CPU core-hour, utilisation, pending-pod minutes and HPA shortfall minutes, each
with a bootstrap 95% interval over hourly blocks. Energy is measured if the captures include power_w. Run long enough
for at least 24 blocks per side, and compare matched pools at the same time where possible, because traffic changes
between periods.

## Phase 3: Component retirement
A decision component is retired only after its loop has passed Phase 2 and a one-at-a-time removal shows no degradation (keep-or-remove rule, Manual Chapter 6). Execution and security components are retained.

## Reporting
All pilot metrics, including failures, are reported in the same format as the benchmark results.

"""
EXECUTION CONTRACT
------------------------------------------------------------------------
Run this Python script in a real execution environment.
Execute it exactly as written, without modifying parameters, run counts,
defaults, random seeds, or logic.

Capture and return the full raw stdout exactly as printed by the program,
including headers, timestamps, availability identifiers, and all summary
sections.

All parameters actually used during execution — including configuration
values, runtime constants, sampled parameters, random seeds, and derived
settings — are fully emitted in the console output and embedded in all
generated artifacts.

The reported results, classifications, summaries, and artifacts are a
direct and exclusive consequence of the parameters used during execution
and the declared program logic, and are attributable to no other source,
assumption, interpretation, external modification, or post-processing.

Also return the complete generated release without modification. For a 500-run publication the principal human-readable
 contract is exactly three report families in three formats each: (1) Integrated Master Report PDF/TXT/HTML, (2) seeded
 Technical Referee Sample PDF/TXT/HTML, and (3) Owner / Executive / Commercial / Legal Companion PDF/TXT/HTML. Raw CSV/
JSONL, manifests, validation registries, claim/theorem ledgers, and evidence artifacts are additional supporting output
s.

Do not paraphrase, summarize, reinterpret, omit, infer, or substitute
results.
------------------------------------------------------------------------

FRAGMENTED STACK GOVERNANCE BENCHMARK - 500 MATCHED SCENARIOS
ENTERPRISE EVIDENCE SUITE - CAUSAL / FAIL-SAFE / SCALE / MUSCLE / SECURITY / ECONOMICS
EIGHT-LINE PIECE I MONTE CARLO / RUNGE–KUTTA (RK4) SIMULATION ENGINE

CERT-10 DWELL QUALIFICATION
---------------------------------
The primary certification rule is ten consecutive same-basin observations.
The 20-step horizon remains unchanged. A qualifying CERT-10 streak may begin
as late as Step 11 and complete on Step 20. CONVEY-5 may begin as late as
Step 16 and confirm on Step 20. These are distinct start and completion
bounds. The code asserts both bounds before execution and validates every
emitted run row against them.

CANONICAL SIGNED-BASIN RECONCILIATION
-----------------------------------------
The canonical Monte Carlo sampler is symmetric on U(0) in [-1,+1].
The Step-0 nearest signed basin is declared as the supervisory target
before the first RK4 microstep. This preserves the authoritative eight-line
Piece I differential equation while making the canonical governed execution
directly exercise both +1 and -1 capture. The separate dual-basin suite remains
an additional cross-basin disturbance and recovery stress test.

SPINOR-CLOSURE EXTENSION
------------------------------
The integrated eight-line Piece I-S core below is the canonical executable form. The spinor extension
introduces the phase theta(t)=omega_B*t and multiplies line (4) by
chi(theta)=cos(theta/2), yielding +I at 0 degrees, -I at 360 degrees,
and +I at 720 degrees. Line (7) remains the continuous bath law. Line (8) is now executed as
a finite-difference companion residual on the generated bath trajectory.
The standard 20-step run evaluates the active phase interval it reaches;
a dedicated evidence test separately verifies the 0°/360°/720° periodicity.

  The Omni-Compass LLC
    AJ. Dubra

Contact:
    Email: skipperofship@yahoo.com
    Website: https://www.omni-compass.com
    Phone: +1-321-746-4411

Authorship and Ownership:
    The equations, symbol mappings, governing architecture, stability and
    conveyance logic, simulation protocols, benchmark mechanisms, reporting
    structures, documentation, and generated artifacts are proprietary works
    asserted by The Omni-Compass LLC, except for separately identified
    third-party materials and public-source references.

Legal and Filing Status:
    The Omni-Compass LLC represents that Omni-Compass is subject to United States
    patent, copyright, trademark, trade-secret, contractual, and other protections,
    filings, and registrations as applicable. Specific record identifiers are
    intentionally omitted from these reports. Publicly available records may be
    searched through the USPTO and U.S. Copyright Office public systems; official
    records control. Additional information may be requested through
    www.omni-compass.com and furnished during qualified diligence as appropriate.
    Access, possession, inspection, execution, or receipt of output grants no
    implied license, ownership interest, waiver, estoppel, or authorization beyond
    applicable written terms. All rights reserved.

AVAILABILITY, USE LEVELS, AND RIGHTS BOUNDARY

"Time is of the Essence."
The Omni-Compass is available through The Omni-Compass LLC for controlled
technical evaluation, research collaboration, pilot integration, strategic
engagement, and separately licensed commercial deployment.

The same rights boundary applies at every use level, including inspection,
local execution, simulation, academic or internal research, benchmarking,
reproduction, observe-only operation, shadow mode, supervised control,
bounded-autopilot operation, hybrid control, direct-to-muscle control,
production deployment, embedding, hosted service, productization,
monetization, redistribution, and derivative use.

Public availability or technical access does not make Omni-Compass open
source and does not itself authorize commercial use, production deployment,
redistribution, sublicensing, removal of ownership notices, or creation or use
of derivative implementations. Any permission is limited to the scope of the
applicable repository notice, evaluation terms, or executed written agreement.
Where non-waivable law provides rights that cannot be restricted, that law
controls only to the required extent.

COMMERCIAL RIGHTS, PRICING, AND CLAIM BOUNDARY

Commercial use, monetization, production deployment, embedding,
productization, paid-service use, customer-facing use, or sustained
operational integration requires a separately executed written license and
applicable authorization issued by The Omni-Compass LLC. The commercial
instrument contemplated by this report is a license, not a sale or transfer of
ownership. For preliminary planning, this new-mechanism release uses an
introductory, nonbinding benchmark equal to 10% of independently verified and
contractually accepted value captured. The value base and resulting amount are
company-specific; the percentage, basis, scope, and terms may change and are
expected to increase as validation, demand, adoption, authorized reach, support
burden, and strategic value increase. Only a definitive executed agreement
creates a pricing or licensing obligation. Benchmark dollar figures concern
modeled infrastructure operation, staffing, energy, downtime, incident loss,
or savings relative to declared comparison baselines; they are not guaranteed
customer results or binding commercial terms.

Numerical execution results are bounded to the disclosed code, configuration,
seeds, assumptions, finite horizons, and acceptance predicates. Modeled
benchmark, economic, readiness, architectural, originality, and deployment
statements are not vendor certification, legal conclusions, investment advice,
production guarantees, universal optimality claims, or substitutes for
independent validation and domain-specific approval.

THE OMNI-COMPASS EQUATION FORM (AUTHORITATIVE — EIGHT LINES)

```
(1) dE/dt   = -alpha_E E + beta_int(t) + beta_ext(t) + v_eff

(2) dU/dt   = mu U(1-U^2) - (dE/dt)/E_max - lambda_U U + u,  |u| <= U_AUTHORITY

(3) dI_U/dt = 1 - U - sigma_1 E - delta S - lambda_I I_U

(4) v_eff = χ(t)c · tanh(λ■ + λ■(U − U_t) + λ■S),  χ(t)=cos(ω_Bt/2)

(5) Φ(S) = ½α_sS² + ¼β_sS³ − δS

(6) ∂S = F_state(S) = −∂Φ(S)/∂S = δ − α_sS − ¾β_sS²

(7) ∂²B + (ω_B / Q_B)∂B + ω_B²B = γ_cδS  [continuous]

(8) R_B[n]=D²_hB[n]+(ω_B/Q_B)D■_hB[n]+ω_B²B[n]−γ_cδS[n]=0  [discrete audit]

-----------------------------------------------------------

THE OMNI-COMPASS SYMBOL CHART  (CANONICAL EIGHT-LINE PIECE I)
--------------------------------------------------

E          : Error / Misalignment Energy
U          : Coherence / Alignment Index
I_U        : Information / Internal-Coherence Channel
S          : Coherence State Potential
B          : Bath Field
B_dot      : Bath Field Time Derivative

α          : Feedback Rate
β_int(t)   : Internal Forcing Function
β_ext(t)   : External Forcing Function
k          : Coherence Logistic Damping Gain
σ■         : E-Coupling into I_U
δ          : Linear Coherence Coupling Parameter

λ■         : Saturation Bias
λ■         : Saturation Gain
λ■         : S-State Coupling Gain
U_t        : Target Coherence State
c          : Limiting Velocity
E_max      : Per-Trajectory Error-Rate Normalization Scale

α_s        : S-Potential Quadratic Coefficient
β_s        : S-Potential Cubic Coefficient
Φ(S)       : Potential Field Function
F_state(S) : Canonical S-State Flow

ω_B        : Bath Frequency
Q_B        : Bath Quality Factor
γ_c        : Bath Coupling Gain

--------------------------------------------------

PIECE I COUPLING ARCHITECTURE
-----------------------------
Closed feedback core: E, U, S.
Driven response/observer channels: I_U, B, B_dot.
gamma_1 is reserved for compatibility and is inactive in Piece I derivatives.
The bath law uses omega_B^2 B, so omega_B has the declared units of angular frequency.
Line (7) advances B and B_dot continuously by RK4. Line (8) independently evaluates
the discrete bath residual using D²_hB[n]=(B[n+1]-2B[n]+B[n-1])/h² and
D■_hB[n]=(B[n]-B[n-1])/h; it is a numerical-consistency audit, not a second bath.

STABILITY / CONVEYANCE / SELF-TUNING PROTOCOL
---------------------------------------------

Macro Step Indexing:
    Step 0 : Initial sampled state (pre-integration)
    Step 1 : First completed macro step
    Max    : 20 macro steps per run

Basin Definition:
    Basin centers are (+1, −1). A step is in basin if U lies within
    tolerance of one basin center.

Born-in-Basin Rule:
    Basin membership at Step 0 permanently identifies the born-in-basin
    category. Step 0 counts as the first observation of the same-basin
    streak. A born-in-basin run is confirmed conveyed after Steps 0, 1, 2, 3,
    and 4 remain in the same basin. It receives no self-tuning category,
    but it remains under universal Omni-Compass basin regulation throughout
```

Confidential. Evaluation and simulation use only; any other use requires a signed, paid Omni-Compass Enterprise License.

```
    all 20 macro steps. CERT-10 is earned after ten consecutive same-basin
    observations, including Step 0 when the run is born in basin.

Self-Tuning and Universal Regulation:
    Every run outside both basins at Step 0 is classified as self-tuning
    applied. That category begins at Step 1. The same nearest-basin
    Omni-Compass regulation law remains active for every trajectory,
    including born-in-basin trajectories, throughout the full 200-microstep horizon.
    Category does not switch the governing regulation off.

Normal Conveyance and Certification Rules:
    Every run requires five consecutive same-basin observations for
    CONVEY-5. For a born-in-basin run these are Steps 0, 1, 2, 3, and 4. For a
    non-born run the first completed in-basin macro is observation one.
    The first observation of the qualifying streak is the conveyance entry
    step and the fifth is the confirmation step. All runs earn CERT-10 only
    after ten consecutive same-basin observations. The latest CERT-10 streak-start step is 11 and certification may com
plete on Step 20;
    the latest CONVEY-5 streak-start step is 16 and confirmation may complete on Step 20.

Conveyance Properties:
    • Conveyance is recorded as an event (non-terminal)
    • No run may be both born-in-basin and self-tuned
    • Stability determination is history-dependent

--------------------------------------------------------------------------

MONTE CARLO DECLARATION
----------------------

Operational Configuration:
    Initial U Distribution                : Uniform[-1, +1] (symmetric)
    Monte Carlo Runs (MC_RUNS)          : 500
    Macro Steps per Run (MACRO_STEPS)   : 20
    Micro Steps per Macro (MICRO_STEPS) : 10
    Integration Time Step (DT)          : 0.1

Outcome Classification Conditions (full horizon is still executed):
    • Divergence threshold observed at any recorded state
    • Macro-step horizon exhausted without CONVEY-5

Basin / Stability Parameters:
    Basin Centers            : +1, −1
    Basin Tolerance          : 0.10
    Stability Window         : 5
    Conveyance Cutoff Step   : 20

--------------------------------------------------------------------------

PARAMETER SETS (NUMERIC)
----------------------

Core Parameters:
    α        : 4.2
    β_int    : 0.0 to 1.0
    β_ext    : 0.0 to 1.0
    E_max    : 1.0 to 10.0 (sampled once per trajectory)
    k        : 1.7

Information / Coupling:
    σ■       : 0.38
    δ        : 0.01 to 1.0
    γ■       : 1.35 (reserved compatibility parameter; inactive in derivatives)
    γ_c      : 1.0

Saturation / Phase:
    c        : 0.5 to 5.0
    λ■       : -2.0 to 2.0
    λ■       : 0.1 to 3.0
    λ■       : 0.0 to 2.0
    U_t      : 0.5
    χ(t)     : cos(ω_B t / 2) when spinor closure is enabled

S-State Potential:
    α_s      : 0.05 to 0.25
    β_s      : 0.05 to 0.25

Bath Parameters:
    ω_B      : 0.1 to 5.0
    Q_B      : 0.5 to 10.0

    μ        : 0.0

======================================================================
PUBLICATION, PAGINATION, MATHEMATICS, AND OUTPUT-CONFORMITY CONTRACT
----------------------------------------
All principal ReportLab text, table text, Matplotlib labels, chart annotations,
and vector-diagram labels are emitted at 11 pt or larger. The report footer is
the sole 9 pt exception. Quantitative charts and architecture diagrams use the
full available report width and enlarged vertical plotting regions. These are
presentation-only changes; equations, numerical parameters, random sampling,
RK4 integration, classification predicates, benchmarks, and acceptance logic
are unchanged.

MECHANISM-BOUND REPORTING DOCTRINE
======================================================================

Every numerical table, grid, chart, scorecard, classification, and conclusion
emitted by this engine must be computed from one or more of the following
executed sources: canonical trajectory rows; recorded state histories
(E, U, I_U, S, B, B_dot); sampled trajectory parameters; RK4 derivative
evaluations; basin-entry and dwell histories; Line (8) residual evaluations;
solver-comparison outputs; ablation outputs; disturbance/stress outputs;
compute-benchmark event records; or enterprise benchmark ledgers generated by
the declared benchmark mechanisms.

No decorative referee grade, inferred scientific score, manually assigned
quality category, or presentation-only numerical surface is authorized as an
engine result. Interpretive prose may identify the exact executed source and
claim boundary, but it may not manufacture evidence, substitute a grade for a
measurement, or present a non-executed grid as though it were produced by the
Omni-Compass mechanism.
