  4  """What each mechanism contributes. The confirmatory setting (tuning/GLOBAL_LEAGUE_PREREGISTRATION.json) against
  5  versions with one mechanism removed, on 30 fresh scenarios per workload (seeds 711001-711030), paired:
  6    gate_off      the six-state engine's equation-(2) push no longer gates releases (push_release = infinity)
  7    no_turn       releases no longer wait for the turning point (Chapters 29-30)
  8    no_tone       released machines are powered off instead of parked (no warm reserve)
  9    no_trend      the dual bath's rate is removed (b = 0: level only, no forecast of the trend)
 10    no_closure    the closure law is removed; machines follow the engine-driven speed governor (the earlier C)
 11  Reported: mean change of every gauge against the full law (positive = the removal made it worse) with a paired 95%
 12  bootstrap interval, plus contradictions (controllers fighting, quick reversals). Usage: python tuning/ablation.py"""

  4  """Physical bound: what a controller with perfect knowledge of the future could achieve on node-hours and machine churn
     .
  5
  6  For each scenario the pods (and their CPU requests) are those produced by HPA 70% (the platforms' setting). A node coun
     t
  7  n(t) is feasible when it holds every pod: n(t) >= ceil(requests(t) / (cores x ALLOC)), within [min, max] nodes. Dynamic
  8  programming finds, for a price lambda on node-hours, the trajectory minimising starts+stops + lambda x node-ticks; swee
     ping
  9  lambda traces the frontier: the fewest starts+stops possible for each node-hour budget. (Boot delay is ignored, which
 10  only favours the bound.) If a competitor's node-hours and another competitor's starts+stops lie below this frontier, no
 11  controller whatsoever can match both, Omni-Compass included.

  4  """Confirmatory run. The single global closure-law setting frozen in tuning/GLOBAL_LEAGUE_PREREGISTRATION.json is run
  5  once on 100 never-used scenarios per workload (seeds 710001-710100) against the seven platforms, every gauge. For each
  6  of the 364 (workload x platform x gauge) cells: the paired mean difference, its bootstrap distribution (10,000
  7  resamples), a two-sided bootstrap p-value, and the Holm-Bonferroni step-down correction across all 364 cells at family
  8  alpha 0.05. A cell is reported better / worse only if it survives the correction and the difference exceeds the 0.5%
  9  practical tolerance (0.5 events for counts); otherwise it is equal. Every earlier held-out round is listed in the outpu
     t
 10  with its seed range. Usage: python tuning/confirmatory.py  ->  tuning/CONFIRMATORY.json
 11
 12  --coord: the same frozen setting with the nervous-system coordination switched on (ClosureLaw coord=True: pods are
 13  stepped first, a machine move opposite to the pod move is vetoed). Fresh seeds 712001-712100, frozen in
 14  tuning/COORD_PREREGISTRATION.json (setting, seeds, SHA-256 of the code) before the first scenario runs. Same 364 cells,
 15  same Holm correction; controller contradictions per arm reported beside the family (not added to it).

"""Can Omni-Compass be equal or better than EACH competitor on EVERY gauge? (development seeds 101-110)

Two questions, answered from one search:
  individually  for each competitor and vessel: is there an Omni configuration with no losing gauge against it?
  all at once   for each vessel: is there one Omni configuration with no losing gauge against every competitor?
Candidate Omni configurations: the frozen fleet-law family with free constants, and the speed-law family
(omnicompass/speed.py); the engine equations are unchanged. A loss is as in tuning/league.py (worse beyond 0.5% and the
paired bootstrap 95% interval excludes zero).
Usage: python tuning/dominate.py N SEED

"""Prototype law v2: two structural changes to how the engine's directive becomes actions (adapter.directive_to_actions
is frozen and is not edited; v2 wraps it).

1. Replicas (direct actuation) are sized with the engine's own sizing equation, the one it uses for nodes:
       r* = ceil(r * load / rho* + kq * q * r)
   and may rise whenever there is backlog, not only when the node decision points up.
2. The power cap moves only when the change exceeds a dead-band AND the equation (2) control push has converged
   (|push| <= push_release), the same gate the engine applies to releasing capacity; raising the cap is never delayed.
"""

"""League table: every competitor against Omni-Compass, one at a time, on every gauge and every vessel.

Rule (the owner's): Omni-Compass must be equal or better than EACH competitor on EACH gauge. A cell is a loss when the
competitor is better by more than the tolerance AND the paired bootstrap 95% interval excludes zero. Every loss goes on
the attack list.

Competitors, each at its documented defaults (fleet plant with response time, fleet/sim_slo.py; vendor arms emulate
documented behaviour, not the vendors' binaries):
  k8s_hpa70_ca   Kubernetes: HPA (70%, the target of every earlier study) + Cluster Autoscaler (= GKE balanced)
  openshift, gke_optimize, aks_nap (= Karpenter, also EKS Auto Mode), turbonomic, cast_ai, spot_ocean
Omni-Compass: one configuration per vessel type (web, multi, batch, gpu), chosen from the candidates below as the one w
ith
the fewest losses on the development seeds. The operator declaring the vessel type is a human-set boundary.
Usage: python tuning/league.py [dev|heldout] [candidates.json]

"""One-command verification of the Omni-Compass package.

  python verify.py           full verification (about 15-30 minutes, single core)
  python verify.py --full-replay   additionally re-runs all held-out scenarios for every arm and requires the
                                   regenerated RUNS.csv and SUMMARY.json to equal the shipped files
  python verify.py --quick   skips the 20,000-case engine comparison, runs a 1,000,000-decision soak
                             instead of 100,000,000, and replays fewer scenarios
