

The Omni-Compass: source code

Owner and author: The Omni-Compass LLC

Version (git commit): 33f06327eb45

Printed: 2026-10-04

Complete source listing.

366 source files, 102,621 lines, 1,835 pages of source in the full listing.

Languages: Python, C++, shell, YAML (GitHub Actions workflows).

Order: the engine (omniconpass/), the controllers (omni_controller/), the C++ twins (cpp/), the fleet and realms models, tools, scripts, deployment, tests, workflows.

4  """The bowl: one smooth law for every muscle, and the plug every muscle is wired through.
5
6  A muscle is a plug with one wire in and one wire out. The plug reads its meters and writes its lever; all the
7  thinking is here, in the brain, written once for every muscle.
8
9  The plug (Plug)
10 read     the service reading (response time, temperature, queue) and the lever as it stands
11 write    one value; the plug clips it to the cover, sends it, and reads back what the device took
12 restore  the lever back to the snapshot, the value read once before the first write; it never moves after that
13 one writer if the lever is found at a value the brain did not write, someone else owns it: the brain stops writing
14           and leaves that value alone (restoring over it would fight the new owner)
15
16 Two bands
17 cover    the outer band, the lever's hard range (the device's or the buyer's lowest and highest setting); every
18           write is clipped to it, so nothing the math does can set the lever outside
19 bowl     the service reading as a position in its band, 0 to 1 (0: calm, 1: the service line); the brain pulls it
20           to the bottom of the bowl, the center (0.5 by default); the walls run to 0.05 and 0.95, and the last 5% on
21           each side is cushion (10% in all) before the line
22
23 The force (Bowl.force), the physics of a ball in a bowl with the right friction
24 pull     K_P x (position - center): gentle near the bottom, harder up the walls
25 push     K_D x velocity: whatever is shoving the position (a load rising, heat building) is met by an equal and
26           opposite push; it is also the friction that stops the ball sloshing past the bottom (with K_D chosen for
27           critical damping it glides to the center and stops, no overshoot, no ringing)
28 smooth   the force is A x tanh(raw / A): a spring near the center that bends over and flattens into its maximum A,
29           never a corner, never a hammer; the same shape the engine already uses for v_eff (omnicompass/core.py)
30 fail up  past the 0.95 wall the up side goes to its full force at once, and the down side may not act until the
31           position is back inside the bowl
32
33 Two forces (antagonist pairs)
34 up       a positive force adds capacity, power, cooling or speed (scale out, raise a clock, start a chiller)
35 down     a negative force takes it back (scale in, lower a limit, warm a setpoint)
36 each side has its own gain (lever units per unit of force), because adding and taking back do not cost the same;
37 a muscle with two wires (a GPU's clock range and power limit) gives each side its own lever; a one-wire muscle
38 carries both directions on its one lever
39
40 The frozen engine (omnicompass/core.py) and its proofs are untouched; this is a separate law, run as its own arm.

==== omnicompass/compass.py (163 lines) ====
1  """The Omni-Compass, computed.
2
3  I read my own state on the compass every decision and say where I am, in the compass's own terms.
4
5  The wheel (Chapter 29). My deviation E, scaled by its ceiling E_max, runs along the horizontal; its rate of change runs
6  along the vertical. A reading is a point on that wheel. Its heading is measured clockwise from north, as on the face:
7
8      +   A       0 deg   rising through rest
9      ■   Δ       45 deg   expansion: above rest and rising, exchange under way
10     >   B       90 deg   peak extension: the turn, where the metric flips (k -> -k)
11     ■   Λ       135 deg  dispersion: above rest and easing, the ceiling holds
12     -   Ω       180 deg  falling through rest
13     ≈   Π       225 deg  compression: below rest and settling into the basin
14     <   Γ       270 deg  deepest compression: the turn at the floor
15     ♦   Ψ       315 deg  re-alignment: below rest and rising, ignition ahead
16
17  The four quadrants are the strokes of the closed circle (Chapters 29-30):
18      I   Expansion     above rest, rising
19      II  Dispersion     above rest, easing
20      III Compression   below rest, falling
21      IV  Re-alignment  below rest, rising
22  The wheel turns I -> II -> III -> IV -> I. Crossing from IV into I is ignition; the turn at peak extension is the
23  metric flip. The state is continuous through every crossing: nothing switches off, nothing restarts.
24
25  The rim carries the 24 letters in their places on the face, 15 degrees each, clockwise from A at north.
26
27  The axle is the structural basin S. Its rest point S* solves equation (6):  $\delta - \alpha_s S - (3/4) \beta_s S^2 = 0$ .
28
29  Closing the circle (Chapter 1, the Unified Circle Principle):
30      X' = G(X),   X(0) in Omega           Omega is the living band: every level inside [0.05, 0.95]
31      G(X) . n(X) <= 0 on the boundary     at a boundary the next move points inward, never outward
32      grad L(X) . G(X) <= 0               the ledger L, the engine's composite storage over all six states
33                                          (omnicompass.storage.composite_V), descends when nothing is forcing it
34      => lim X(t) in M*                   the state settles into the basin
35  I check all three every decision and report them. The ledger may rise while outside load forces me; I report that as
36  forcing, never hide it.

==== omniconpass/conveyance.py (101 lines) ====
1  """Conveyance law: moving a conserved budget ("juice") between organs.
2
3  Manuscript sources (interpretation of the English, not only the symbols):
4  Ch. 29 §8   $E_{\text{system}} = E + U + S + B$ ,  $dE_{\text{system}}/dt = 0$  over the cycle: "Energy redistributes. Energy reorganizes.
5             Energy does not diverge." -> the budget is conserved, only moved
6  Ch. 31 §4  "When E grows locally, B increases to distribute gradients." -> flow runs down the gradient of need
7  Ch. 31 §5  stability requires  $\text{Re}(\lambda_{d_i}) \leq 0$  -> the flow must provably converge
8  Ch. 30 §5-7 ignition is a "redistribution surge ... controlled release", with state continuity (no discontinuity)
9             -> the reserve is released continuously
10 Ch. 29 §6   compression: "backpressure develops through S ... structured inward rotation"
11             -> surplus is pulled back smoothly
12
13 The law. Organs  $i$  hold allocations  $a_i$  of a budget  $A$  (watts, cores, ...), have need  $d_i$  (the budget that would serve
14 their work at the engine's utilisation target  $\rho$ ), and a deficit ("local deviation")
15  $e_i = d_i / (\rho a_i) - 1$  ( $> 0$  needs juice,  $< 0$  holds surplus)
16 The redistribution mediator moves budget by the replicator flow
17  $da_i/dt = \kappa a_i (e_i - e_{\text{bar}})$ ,  $e_{\text{bar}} = \sum_j a_j e_j / A$ 
18 Properties (proved in docs/CONVEYANCE_LAW.md, checked in tests/test_conveyance.py):
19 P1 conservation  $\sum_i da_i/dt = 0$  exactly: the budget is moved, never created
20 P2 gradient flow it is the Shahshahani gradient of  $F(a) = \sum_i (d_i / \rho) \ln a_i$  on the simplex  $\sum a_i = A$ ;
21  $F$  is strictly concave, so  $F$  rises monotonically (Lyapunov function)
22 P3 convergence unique equilibrium  $a_i^* = A d_i / D$  ( $D = \sum d_i$ ): every organ at the same deficit  $e^*$ ,
23 reached exponentially:  $da_i/dt = (\kappa/\rho)(d_i - a_i D/A)$ , rate  $\kappa D / (\rho A)$ , and the
24 linearisation has eigenvalues  $-\kappa D / (\rho A) < 0$  (Re( $\lambda_{d_i}$ )  $\leq 0$ , Ch. 31 §5)
25 P4 bounds organ floors and ceilings (device minimum, TDP) are kept by projection; budget an organ cannot
26 take because it is at its ceiling returns to the others (water-filling), and budget left over
27 when every organ is at its need is held back as reserve, not spent
28 Reserve (Ch. 30 surge):  $R$  = the budget needed to cover the demand rise the rate tracker projects over one actuation
29 delay; released continuously to organs whose deficit stays positive after the flow."""

4  """The master switch: one OFF for the whole harness, not one muscle at a time.
5
6  Every Omni-Compass governor on a machine (the Kubernetes controller, the GPU governors, any muscle they drive) obeys on
7  switch, in a human hand:
8
9  OFF  the switch file exists (OMNI_MASTER_OFF, by default /tmp/omni-compass/OFF). Every running governor sees it at i
10 ts
11     next decision, puts every setting it ever wrote back to the value it read before its first write, reads each on
12 e
13     back, writes its last audit line and exits. No governor starts while the switch is OFF.
14 ON   the switch file is removed. Nothing restarts by itself: a governor runs again only when someone starts it.
15
16 The switch is also pulled from the command line, which signals every registered governor at once so none waits for its
17 next decision:
18
19     python3 tools/omni_switch.py off [--reason TEXT]    turn the whole harness off, wait for every governor to restore
20                                                         allow governors to be started again
21     python3 tools/omni_switch.py on                    OFF or ON, and every governor running
22     python3 tools/omni_switch.py status
23
24 A governor that cannot read the switch (a filesystem it cannot reach) treats that as OFF: when in doubt, hand back.
25
26 If a governor dies without handing back (killed outright, the machine crashed, it hung), nothing it wrote may be left
27 in place. So every governor records, before its first write, the exact commands that put every setting back, and
28 renews a lease every decision. The watchdog finds any governor whose process is gone or whose lease is older than its
29 limit and runs those commands for it:
30
31     python3 tools/omni_switch.py watchdog [--stale 60] [--every 10]    keep watching (run it as its own service)
32     python3 tools/omni_switch.py watchdog --once                      one pass

4  """Math-driven actuation: the Omni-Compass equations move the system directly.
5
6  The frozen governor (adapter.Governor) evolves the equations open-loop (u = 0) and reads only a few derived numbers.
7  Here the equations are closed-loop and their own quantities ARE the actuator commands. No equation is changed; the
8  integrator, parameters and observation map are the frozen ones (omniconpass/core.py, omniconpass/adapter.py).
9
10 Per decision
11 1. sense      x <- assimilate(x, observe_vector(telemetry))          (the frozen observation map)
12 2. evolve     x <- macro_step(x, target = +1, macro_dt = clock)      equations (1)-(7) with equation
13                                     (2)'s controller ON: u = clip(-f_U(x) + 12 (1 - U), -25, 25) holds the healthy basin U = +1
14 3. read the   effort w = integral |u| dt / (25 clock)   in [0, 1]: how hard the math had to work to stay healthy
15    math       need    I_U                                equation (3): unrelieved need, slow memory
16              tide    B, B_dot                            equation (7): the bath, second order, anticipates
17              drive    v_eff                             equation (4): the tanh-bounded drive
18 4. actuate    capacity n = ceil(fit (1 + g_w w + g_I max(0, I_U) + g_B max(0, B_dot))) machines
19                                     (released one at a time only while w <= w_release: the math reports calm)
20              pods    HPA target rho = clamp(rho0 - k_w w - k_I max(0, I_U), rho_min, rho0)
21              power    cap = clamp(1 - g_cap max(0, B) + 2 w, cap_min, 1) (the bath lowers power only when calm)
22    clock: engine time advanced per decision. It sets how fast the math moves relative to the system: the bath's
23    natural period is 2 pi / omega_B = 6.28 engine units, i.e. 6.28 / clock decisions.

4  """Nervous system: one engine, many muscles.
5
6  Each muscle is a connector with five parts (domain map):
7      afferent sense
8      engine  shared six-state field (not duplicated)
9      efferent push
10     reflex  shield / bounds before push
11     kill    return that muscle to its native controller
12
13 Status:
14     wired    sense and push are executed in this tree
15     sensed   telemetry is accepted; push is not issued
16     open     connector registered; no plant; no push
17
18 This module does not replace adapter.Governor. It sits around it:
19 afferents merge into the observation vector the governor already understands;
20 efferents are tagged by muscle so a kill is per-nerve, not a mystery write.

==== omnicompass/nervous_system.py (158 lines) ====
1  """The supervisory nervous system: one evolving engine state grants authority to every organ family.
2
3  Omni-Compass does not replace the specialist controllers. Each keeps its own mechanism:
4  - the HPA and VPA size pods;
5  - the Cluster Autoscaler and Karpenter size node pools;
6  - Linux schedutil picks CPU frequency;
7  - NVIDIA DCGM manages GPUs;
8  - rollout controllers and routers do their own work.
9
10 The nervous system decides, from one shared state, the envelope inside which each of them may act.
11
12 Inputs, all from the six-state engine (omnicompass/core.py, via the governor), and nothing tuned per organ:
13 kappa convergence = 1 if push <= push_release, else push_release / push. This is the equation-(2) gate made
14                    continuous: the further the engine is from its basin, the less it may give back.
15 h      basin health = clamp((U - U_gate) / (1 - U_gate), 0, 1)
16 sigma stress ratio = S / S*, where S* solves delta - alpha_s S - (3/4) beta_s S^2 = 0 (equation 6)
17 nu     unmet need   = max(0, I-U) (equation 3)
18 calm   = kappa * h * (1 - clamp(sigma - 1, 0, 1)) * (1 - clamp(nu, 0, 1))
19         in [0, 1]; 1 means fully settled
20
21 Authority per organ:
22 expand   may the organ add capacity or performance. Always yes, except during a security hold.
23 contract may it give capacity or performance back. Only when calm >= the organ's reversibility threshold
24          (theta_pods 0.5, theta_nodes 0.7: a node costs a boot to reverse) and the SLO is clean.
25 step     fraction of the organ's surplus it may shed this decision. Equals calm.
26 envelope for continuous organs, the allowed range:
27          cpufreq ceiling (fraction of cpuinfo_max) in [1 - 0.35 calm, 1];
28          GPU power limit (fraction of max) in [1 - 0.30 calm, 1];
29          site power cap in [0.65, 1];
30          traffic-shift fraction in [0, 0.5 calm];
31          cooling supply-air setpoint (C) in [18, 18 + 9 calm].
32          Heat above 0.96 forces the frequency and GPU ceilings down to 1 - 0.35 x excess.
33 batch    admit held work only if calm >= 0.5 and power stress < 0.9; pause pausable work if sigma > 1, power
34          stress >= 0.95, or heat >= 0.96.
35 rollback the engine's rollback authorisation (S high, U falling, or a security hold).
36
37 Global rules, applied last:
38 - observe: every authority is computed and logged; execute is False everywhere.
39 - kill: no authority at all.
40 - security hold: no capacity organ may expand. Cooling is the one protective organ: "expand" there means more
41   cooling, which adds protection and no capacity, so it stays allowed.
42 The safety shield (omnicompass/shield.py) stays downstream and can still veto any action.

4  """Speed-first allocation: the frozen six-state engine, a law that never trades response time for energy.
5
6  The frozen fleet law (adapter.AllocationLaw, FLEET_MODE) uses one number, rho*, both as the HPA target (how busy each
7  pod may run) and as the node-sizing target (how busy each machine may run). Saving machines therefore always meant
8  running pods hotter, which is where response time was lost. This law separates the two:
9
10 pods      HPA target = rho* from the engine (equation: rho* = clamp(rho0 - kI I_U - kE E, rho_min, rho0)), with
11 speed constants (rho0 near the latency knee) and the response-time nerve feeding the queue observation
12 machines  sized to what the pods ask for, not to how busy they are:
13           n_up   = ceil(requests / (cores * ALLLOC) * (1 + headroom_up)) + ceil(kq * q * n)
14           n_keep = ceil(peak requests over the last `window` decisions / (cores * ALLLOC) * (1 + headroom))
15           added at once when n < n_up (a pending pod costs response time);
16           removed one per decision only when n >= n_keep + band for dwell decisions, no sooner than after_add
17           decisions after an addition, and only while the engine's equation (2) push <= push_release
18 ahead     while requests are rising, n_up += ceil(antic * trend * n), trend = relative rise over antic_lag
19           decisions (anticipation: machines boot before the pods that need them are created; antic = 0 disables)
20 power     cap = 1 whenever work is waiting or pods are busy above cap_busy; otherwise cap_idle
21           (a cap slows service: S = S0 / cap, so capping a busy machine always costs response time)
22
23 The engine state (E, U, I_U, S, B, B_dot) is evolved by omnicompass.core unchanged; only this mapping is new.

4  """The verdict: Omni-Compass moves a knob only where it measures that the muscle is no worse for it.
5
6  Omni-Compass sits on top of a muscle that already works (a card's firmware, an autoscaler, a chiller's loop). It does not
7  replace that muscle, and it has no reason to move the muscle's knob unless moving it costs the muscle nothing. The
8  verdict is how the brain finds that out, on the muscle itself, before it acts and again from time to time:
9
10     steps      the knob's settings from native outward, in whole steps (step 0 is native: the muscle as it runs alone)
11     cost        what each setting costs the muscle's own work, measured per piece of work (a card: the milliseconds it spends
12
13     probe       on one request, the wait in the queue left out, so more traffic is never mistaken for a slower card)
14                while the service is calm, a paired trial: first the knob at native until min_samples pieces of work are
15                measured (the reference, fresh, under the same traffic), then at one step past the deepest step already
16                allowed until min_samples more are measured
17     judge       the trial step's median cost against the reference's: no higher (within the measurement's resolution,
18                tolerance) and the step is allowed; higher and it is refused, the knob goes back, and that step is not tried
19
20     allowed     again until recheck decisions have passed (the work may have changed). A trial that sees the service leave
21                calm is abandoned, and the knob goes back at once
22                the bowl may move the knob only between native and the deepest allowed step; where no step is allowed, the
23                verdict is "left native" and the knob is never moved
24
25     stepwise    for a knob that is slow to move back (a machine given back takes minutes to return), incremental=True runs
26                the reference at the deepest step already allowed instead of at native, and judges the trial step against
27                both that reference and the cost first measured at native, so steps can never add up past the allowance
28
29 The verdict never makes the knob more aggressive than the law: it only narrows where the law may go. Every probe and
30 every judgement is returned to the caller for the audit.

==== omni_controller/controller.py (843 lines) ====
1  """Omni-Compass live controller for a real Kubernetes cluster.
2
3  Modes
4  observe    read the cluster every interval, run the fleet-mode governor in OBSERVE, log every decision; no writes (default)
5  target     additionally patch each HPA's CPU averageUtilization to rho* (bounded, rate-limited); the Cluster Autoscaler
6  r and      all node management remain unchanged
7  nodepool   additionally size one node pool to the governor's recommendation through --node-scale-cmd, a command template
8  te         such as "aws autoscaling set-desired-capacity --auto-scaling-group-name POOL --desired-capacity {n}"; the
9             Cluster Autoscaler must not manage that pool
10 Laws (--law)
11 governor   (default) the engine's allocation law sets the HPA target (rho*) and the closure law or the governor sizes
12 the pool   the bowl law (omnicompass/bowl.py) holds the service in its band, read as the GPU bowl reads it: the mean
13 bowl       response time of the latency window between the bare service time (a tenth of --slo-ms) and --slo-ms, held
14 at         --bowl-center (0.4); p95 at or past the SLO, a blind sense or pods waiting for a place read as past the wall.
15 l. Its push and pull move two levers: each HPA's CPU target inside its cover (from 60% of the operator's target up to the operator's own, never tighter than native, so it only ever adds pods and gives
16 them       back) and the node pool (one machine back only while the force is clearly down, the position below the center
17 er         and the nervous system's release gate open; past the 0.95 wall, one machine up at once). The verdict
18 (omnicompass/verdict.py, stepwise) decides how many machines may be given back at all: while the service is calm, one more machine is given back on trial and the response time of the requests served without it is set
19 t          against the requests served just before and against the cluster as it ran on its own at the start; at most
20 --allow slower and that machine stays given back, slower than that and it is taken back and not tried again
21 for --verdict-recheck decisions. Where no machine passes, the pool stays as the cluster runs it alone. The
22 six-state engine still runs every decision: it grants the authority, feeds the release gate and the compass
23
24 /          and is audited
25 Safety
26 every node action passes through the shield (bounds, step limit); the recommendation never falls below what the CPU
27 requests of running and pending pods, or current usage, need, and capacity required by that floor is added in one step
28 p          (the step limit applies only to the governor's own adjustments); --dry-run logs intended writes without executing the
29 m; creating the kill file (or
30 setting OMNI_KILL=1) restores every HPA target this controller changed, runs --node-restore-cmd if given, and returns
31 to         observe; every decision and action
32 is appended to the audit log.
33 Requires kubectcl on PATH with access to the cluster (metrics-server for kubectcl top).

404             replicas = current x busy / target, read from the live queue instead of CPU averages a minute old.
405
406             Busy comes from queueing physics: a replica serving requests in processor sharing answers in  $R = S / (1 - u)$ ,
407             so  $u = 1 - S / R$ , with  $S$  the bare service time (the fastest tenth of the window's requests, those with no queue
408             ahead) and  $R$  the mean response of the same window. The operator's target is a share of the pod's CPU request; t
he queue runs on
409             its limit, so the same promise in queue terms is target x request / limit. The reflex only raises the replica
410             floor to what that rule needs now and hands it back the moment the queue no longer needs it: no padding, no new
411             target, the operator's own promise met sooner. Zero cluster reads while the queue is calm.""

4  """Omni-Compass on one GPU through two wires: the bowl law (omnicompass/bowl.py) on a real card.
5
6  The card keeps its own control: NVIDIA's firmware still boosts and still protects the chip. Omni holds two settings the
7  card already accepts, and nothing else:
8  up wire   the clock ceiling: how high boost may climb (nvidia-smi -lgc MIN,MAX; -rgc resets it)
9  down wire the power limit: the lid above what that ceiling draws (nvidia-smi -pl W)
10
11 Every decision (--interval seconds):
12     read      nvidia-smi: power.draw, temperature, utilization, power.limit, clocks.sm; the workload's response times
13     position   the service as one place in its bowl, 0 calm to 1 the line: response time only (the mean over the last
14     t          --latency-window-s, between a tenth of the line, the bare service time, and the line; the 95th percentile a
15               or past the line, or a failed request, is past the wall). A card that is busy is doing its work; being busy
16               is not a breach and is not read as one
17     native     what the card does on its own, learned from its own meter before the bowl may lower anything: while the
18               ceiling is at the top and the card is busy, its clock and its draw (the clock its own power limit holds it
19               at, and what that costs). Until --learn-samples busy readings are in, the ceiling stays at the top
20     race       while the card is saturated (utilization at or over --race-util: work is waiting), the ceiling goes to the
21               top and the lid to the start limit, so a burst is served at full speed; the bowl paces only the slack
22     force      the bowl: pull to the center, push against what is rising, tanh-bounded; past the 0.95 wall: fail up
23     verdict    how far the ceiling may go (omnicompass/verdict.py): while the service is calm, a paired trial: the ceiling
24               at the top until --verdict-samples requests are measured, then one 15 MHz step past the deepest step
25               already allowed until as many again are measured; the card's own time on each request (the workload's
26               service_ms, the wait in the queue left out) is compared: at most --allow slower and the step is allowed,
27               slower than that and it is refused and not tried again for --verdict-recheck decisions. Where no step
28               passes, the ceiling stays at the top: the card runs as it does alone
29     law        down gain 0.0125, the bowl's center at 0.4, the speed floor at the card's own busy clock (amendment 8)
30     steady     while the card is saturated against its own power limit (work waiting and the draw at the limit), the
31               firmware boosts a step, hits the limit and is knocked back: a sawtooth. The ceiling is then held at the
32               card's own busy clock under that limit (what the sawtooth averages to), so the same watts serve the work
33               without the knock-backs (amendment 9). It never holds under that clock, and blind always fails up
34     write      up wire: the ceiling moves by the force (fast up, gently down), inside its cover: from the card's own busy
35               clock (never slower than native while there is work) to the top; down wire: the lid at the card's own busy
36               draw plus --lid-headroom, never under it and never over the start limit, inside the declared envelope;
37               fail up: ceiling to the top and the lid to the start limit at once
38     guards     blind (meters unreadable, response times stale): fail up; heat (the card reports a thermal or hardware
39               slowdown): never tighten; one writer: a power limit neither mine nor the start means another writer, so
40               observe only from then on and exit 5; read-back: every write is read back
41     restore    on exit, kill file or SIGTERM: clocks reset (-rgc) and the power limit back to the start, read back
42
43 The audit (--audit) carries the same records the bench reads from the one-wire governor (snapshot, decision with
44 telemetry and decided_by, write and actuator for each power-limit write, restored), plus clock_write records.
45 Exit: 0 clean, 3 restore failed, 4 a write refused, 5 another writer.

==== omni_controller/gpu_governor.py (529 lines) ====
1  """Omni-Compass on one GPU box, no Kubernetes: the engine reads each GPU's own meter and may lower its power limit.
2
3  Every decision (--interval seconds), for each GPU in --gpus:
4      sense      nvidia-smi: power.draw, temperature.gpu, utilization.gpu, power.limit (the device's own readings)
5                  the workload's response-time file (--latency-file, elapsed_seconds,latency_ms,ok) if given
6      engine      the Omni-Compass governor, throughput law (omnicompass/adapter.py): load = utilization, power stress =
7                  draw / the limit found at start, heat = temperature / --temp-limit, queue = response-time pressure.
8                  Its directive power_cap is the share of the start limit the GPU may draw.
9      shield      limit = max(cap x start limit, draw x (1 + --headroom), --min-share x start limit, the device's minimum
10                  limit), never above the start limit; whole watts; a change under --min-change-w is not written.
11                  --min-share bounds the slowdown: a card held at that share of its limit runs a burst only a little slower.
12      busy gate   utilization (smoothed over decisions) at or above --util-gate: the start limit. A busy card is the
13                  bottleneck; slowing it grows the queue faster than it saves energy. The cap returns once utilization is
14                  back under the gate less --util-band.
15      reflexes    a blind sense (nvidia-smi unreadable, or the response-time file stale or empty): the start limit, at once
16                  a response-time breach (p95 > --slo-ms), and for --slo-clear decisions after it: the start limit, at once
17      read-back   no new write until the last one is read back from the device (power.limit within 1 W of what I wrote)
18      enforced    the card obeys enforced.power.limit, which another authority (a lower board or system limit) can hold under
19                  the limit I request. The engine senses the enforced limit; each write is read back at once (requested,
20                  return code, power.limit, enforced limit, delay), and enforced under requested is recorded as an override.
21                  A driver without enforced.power.limit: power.limit is used and the snapshot says so.
22      speed lock  (--baseline-file, from tools/gpu_baseline.py on a run without Omni): the limit is set by response time
23                  alone. Over the last --lock-window-s of the response-time file, the mean, 95th and 99th percentile are each
24                  divided by the baseline's at the same arrival rate; the worst of the three is the speed ratio. The line is
25                  1 - --speed-gain (0.99: at least 1% faster than without Omni). Above the line: the start limit, at once.
26                  Under the line less --lock-margin: lower by --lock-step x start, times the slack in margins (up to
27                  --lock-boost), at most once per --lock-hold-s (the window must see the step before the next). Between: held
28      . Never under --lock-floor x start.
29                  Speed won elsewhere (CPU conveyed to the serving pods, shorter queues) shows as a ratio under the line,
30                  and the lock spends it on watts; with nothing won elsewhere it holds the start limit.
31      one writer  the limit must be what I last wrote (or the start limit). Any other value means another writer: I stop
32                  writing for the rest of the run (observe only), record "foreign_writer", leave its limit alone on kill
33                  (restoring would fight it), and exit 5 so the bench marks the run invalid. Two controllers on one limit is
34                  how production is lost.
35      heat        the device reporting a thermal or hardware slowdown (clock-limit reasons 0x8, 0x20, 0x40, 0x80): never
36                  tighten; the limit may only stay or rise (fail up).
37      envelope    every decision records every rule that held the engine's request back ("blocked_by") and the one that
38                  decided ("decided_by": engine, a floor, the busy gate, a reflex, heat, or the speed lock), so a limit that
39                  did not move names its cause, and a result is credited to the rule that produced it.
40      envelope    --floor-w, the buyer's declared lowest watts (the confirmation run requires it, scripts/gpu_paired.sh
41      floor       ENVELOPE): the limit is never set under it. The highest watts are the limit read at start.
42      outer       when the card's own controller (board, BMC or system policy) already holds enforced.power.limit under the
43      holds       limit I set, a lower write that stays above that enforced value would change nothing the card does: it is
44                  not written ("outer_controller_holds"). Only a write that would actually bind, or a return upward, goes out
45      .
46      Modes
47      watch       everything above is computed and audited; nothing is written (the control arm)
48      cap         the limit is written with nvidia-smi -i <gpu> -pl <w>. Refused at start unless every GPU reports
49                  power.management Enabled. A write the device refuses (nonzero return) ends the run: recorded, the start
50                  limit restored, exit 4, and the bench marks the arm invalid. No clock locks are ever written.
51      Kill switch
52      the kill file (or SIGTERM) restores every GPU to the limit read at start, reads it back, and exits.
53      The start limits are recorded first in the audit ("snapshot": power.limit, enforced.power.limit, default, min,
54      _max, persistence mode, power management, per GPU).

==== omni_controller/muscles.py (680 lines) ====
1  """Live muscles for the Kubernetes controller beyond HPA and nodes.
2
3  Each muscle pulls (afferent) and pushes (efferent) through kubectl, records what it changed so the kill switch can hand
4  the muscle back, and tags every write with its muscle name in the audit log.
5
6  power_cap    push: CPU limit of each running pod of the capped deployments = base limit x the governor's power cap,
7               resized in place (no restart; Linux CFS quota throttles the containers for real); pull: power from --powe
r-cmd
8  heat         pull: thermal state from the harness heat law driven by live power stress (modelled: kind has no thermome
ter)
9  security     pull: ConfigMap key "hold" == "true" means a security hold; the shield then blocks every expansion
10 rollout      push: pause a deployment's rollout while the governor does not permit change; resume it when it does;
11              undo a rollout that has exceeded its progress deadline when the governor authorises rollback
12 batch        push: admit (unsuspend) held batch Jobs, one per decision, only when change is permitted and there is loa
d
13              and power headroom; running Jobs are never suspended
14 latency      pull: 95th-percentile response time over the last --latency-window-s from --latency-file (CSV written by
15 scripts/latency_probe.py); pressure max(0, p95 / --slo-ms - 1) enters the engine as queue pressure
16 cpu_pstate   hardware connector. pull: --rapl-cmd prints package watts (e.g. from /sys/class/powercap/intel-rapl);
17              push: --cpufreq-cmd with {khz}, the frequency ceiling = max frequency x power cap (e.g. writing
18 scaling_max_freq with scripts/cpufreq_ceiling.sh {khz}, see hardware/SCHEDUTIL.md, or `cpupower frequency
-set -u {khz}khz`); kill runs it with the maximum frequency
19 gpu          hardware connector. pull: --gpu-query-cmd prints "watts,celsius" (e.g. `nvidia-smi
20              --query-gpu=power.draw,temperature.gpu --format=csv,noheader,nounits`); GPU temperature / --gpu-temp-limi
t
21              feeds the heat sense; push: --gpu-power-cmd with {w}, the power limit = max limit x power cap
22              (e.g. `nvidia-smi -pl {w}`); kill restores the maximum limit
23 rightsize    push: each running pod's CPU *request* follows its measured use x (1 + headroom), resized in place throug
h the
24 hile         pods/resize subresource (no restart); never above the limit, never below --rightsize-min-m; no decrease w
25 hile         the SLO is breached, no increase during a security hold; kill restores every original request
26 coldstart    push: a deployment with no work waiting (ConfigMap key "queue" == 0, the queue a KEDA scaler would read)
for
27              --coldstart-idle decisions is scaled to zero; it is scaled back to its recorded replica count the moment
28 work is waiting; kill restores the recorded count
29 batch_pace   push: while power stress or heat is high, one running Job labelled omnicompass.io/pausable=true is suspen
ded
30              per decision (checkpointed training pauses instead of the site going over its limit); it is resumed when
31 stress and heat are back down; kill resumes every Job Omni paused
32 contain     push: an agent namespace whose measured CPU use exceeds --contain-cpu-m, or any namespace during a securi
ty
33 the          hold, gets a ResourceQuota (limits.cpu = budget) and its running pods' CPU limits are scaled in place so
34 the          total fits the budget; lifted when use is back under budget; kill deletes the quota and restores the limi
ts
35 cooling       facility connector. push: --cooling-cmd with {c}, the supply-air setpoint moved between --cooling-min-c a
nd
36              --cooling-max-c by the heat state (warm setpoint while cool, saving chiller energy; cold setpoint as heat
37 rises); kill runs it with --cooling-restore-c
38 Hardware connectors are off unless their commands are given (not available on CI runners); the mechanism is the same.

358
359         A serving pod's CPU limit is a quota: a request that needs more CPU than one quota period allows waits for the
360         next period, while the machine it runs on sits idle. That wait is energy withheld from the work, not saved: the
361         request uses the same CPU-seconds either way. So each machine's idle CPU is conveyed to the serving pods on it:
362
363             c_i = min( max(L_i, (0.95 A_j - Q_j) / |P_j|), 0.95 A_j )
364
365         A_j the machine's allocatable CPU, Q_j the requests of every other pod on it, P_j the serving pods on it, L_i t
he
366         operator's own limit. The machine's last five percent is never handed out (the living band), a pod never gets
367         less than its operator gave it, and the requests (what the scheduler and the autoscaler read) are untouched.

```

```

368         Resized in place through pods/resize: no pod restarts. No expansion during a security hold. The kill switch
369         returns every pod to L_i.
370
371         Conveyance is on by default. It moves no work: the same requests run with less waiting. (The +26% CPU seen on
372         kind is more requests served, because that load is closed-loop, not waste.) Optionally, --convey-on (a share
373         of --slo-ms) engages it only once the 95th-percentile response time reaches convey-on x SLO and releases it
374         below convey-off x SLO, returning every serving pod to L_i; a blind latency sense engages it (service first)."""

4  """Replay a cluster capture (capture/kube_capture.sh schema) through the frozen fleet-mode governor in OBSERVE.
5
6  The recommended fleet is carried forward as the governor's own counterfactual state (the node count it would have
7  reached), with load re-expressed against that fleet; the plant's response to the recommendation is not modelled.
8  Outputs, per decision (every FLEET_DECISION_SECONDS): the observed node count and Omni-Compass's recommended node count
9  ,
10 power cap and HPA target, with the scheduling floor (never fewer nodes than running pod requests need). The summary
11 compares observed node-hours with recommended node-hours and, if a node power model is supplied or power was captured,
12 an estimated energy difference. All outputs are counterfactual recommendations; nothing is applied to the cluster.

==== fleet/harness.py (147 lines) ====
1  """Fleet control-plane harness at 15-second resolution.
2
3  Plant: homogeneous node pools, workloads with CPU requests and actual usage, fluid request packing, per-workload
4  backlog, node boot delay (identical for every arm), power (idle + dynamic x utilization, scaled by power cap, PUE),
5  first-order thermal response, site power limit.
6
7  Execution layer (documented behaviour, not the upstream binaries):
8  metrics-server  per-workload usage / request, published every 15 s from the previous tick (15 s lag)
9  HPA              desired = ceil(current * metric / target); no change while |ratio - 1| <= 0.1; scale-up limited to
10                  max(4 pods, 100%) per 15 s; scale-down uses the highest recommendation in the last 300 s
11  ClusterAutoscaler scan every 10 s (every tick here): add nodes for pending requests; remove one node when request
12                  utilization < 0.5 for 10 min, not within 10 min of a scale-up
13  Karpenter-lite  add exactly the nodes pending requests need; remove a node whenever the remaining nodes hold all
14                  requests at <= 0.9 packing, checked every 30 s
15  Vessels:
16  web             HPA-scaled services, diurnal load with bursts
17  batch           job queue (no HPA): jobs request cores for a duration

4  """Fleet simulation with a response-time gauge and a response-time nerve (speed-first mode).
5
6  fleet/sim.py is frozen by results/fleet/PREREGISTRATION.json and has no response-time gauge: its scoring checks that
7  work finishes and backlog stays small, but never how long a request waits. This module runs the same plant, the same
8  HPA, Cluster Autoscaler and Karpenter-lite, the same boot delay and power model, and adds:
9
10 response time    per workload and tick,  $R = S + W_q + W_{backlog}$ , where
11                   $S = S_0 / cap$  service time (a power cap slows the CPU)
12                   $W_q = S * u^{(\sqrt{2(c+1)} - 1) / (c(1 - u))}$  queueing delay, Sakasegawa's M/M/c approximation,
13                   $c = \text{scheduled pods}$ ,  $u = \text{demand} / \text{scheduled capacity} (\leq 0.99)$ 
14                   $W_{backlog} = \text{backlog} / \text{capacity} * \text{TICK}$  time to drain work already waiting
15                   $S_0 = 100$  ms. Gauges: demand-weighted p95, p99 and mean over every (tick, workload).
16                  Job vessels (batch, gpu) have no request queue:  $R = S + W_{backlog}$  (job wait).
17 latency nerve    (omni arms, when  $lat\_gain > 0$ ) the governor's queue observation becomes
18                   $\max(\text{queue}, lat\_gain * \max(0, R_{recent} / (slo\_mult * S_0) - 1))$ ,  $R_{recent} = \text{worst demand-weighted}$ 
19                  response time over the ticks since the last decision. The engine equations are unchanged.
20
21 Arm names and behaviour are those of fleet/sim.py; k8s_hpa50_ca (HPA target 0.5) is added because 50% is the
22 target of the live lab workload. With  $lat\_gain = 0$  and the frozen fleet law, omni_fleet here reproduces the
23 frozen omni_fleet trace (checked by tests/test_sim_slo.py).

4  """The bowl law on every realm muscle (omnicompass/bowl.py): each plant's knob held by its own bowl.
5
6  Each plant's service is read as one position in its bowl (0 calm, 1 the line): the worst of its queue or lateness, its
7  load above half, and, for a storage site, its draw on the grid connection above half. The last period in violation
8  reads as past the wall (fail up). The bowl's force moves the knob: a positive force adds capacity, power, cooling or
9  protection, a negative force gives it back, each knob inside its own cover. At the kill every knob returns to native.
10
11 Knob by plant (the override key the plant already obeys, its native value, its cover, and which way is "more"):
12     compute_pool    power: limit share 0.4-1; replicas-type: the HPA target held at native (loosening it past the
13                     operator's own costs the service time, the same rule as the card's speed floor); machine pools: one
14                     machine released while the force is clearly down and the machines left cover the recent peak with
15                     margin (RELEASE_MARGIN); admission: native
16     thermal_zone    setpoint between the band's stress (colder, more cooling) and calm ends; units: one released while the
17                     force is clearly down; power: 0.5-1
18     energy_storage   reserve between the band's ends (a lower reserve gives the battery to the site); power: native
19     motion_axis      speed and effort: 0.4-1
20     process_loop     setpoint from native toward the band's calm end; actuator range 0.3-1; power 0.4-1

4  """A GPU card on its real physics, its own firmware, and the two-wire plug (evidence class S: a model, not a meter).
5
6  The card
7  clock      f, a share of the top clock (1.0), moved by the firmware in bins of 0.9% (about 15 MHz on a 1.7 GHz part)
8  power      P = idle + leakage(T) + P_dyn x busy x f x V(f)^2, with V(f) = 0.6 + 0.4 f: dynamic power rises with the
9             clock and with the square of the voltage the clock needs, so the top of the clock range costs the most
10 heat      C dT/dt = P - (T - T_amb) / R_th; leakage rises with temperature
11 work      requests arrive (a slow wave, bursts, noise, drawn from the seed); the card serves f x mu per second;
12            a request's response time is its wait plus its service time
13
14 The firmware (native, what ships on the card), 50 times a second
15 boost     while there is work and room, raise the clock one bin, up to the clock ceiling
16 hammer    while the draw is over the power limit, or the chip is over its slowdown temperature, drop three bins
17 So the clock saws against the limit for as long as the work keeps coming: up a bin, knocked down three, up again.
18
19 The work
20 memb      the share of a request's time at the top clock spent waiting on memory, which does not speed up with the
21            clock: 0 is compute-bound work (large matrix products, the bench's pinned workload), 0.85 is typical of AI
22            token generation (each token streams the model's weights from memory). The card serves 1 / ((1 - memb) / f
23            + memb) of its top speed
24
25 The arms: each base alone, and the same base with Omni-Compass on top (Omni never runs the card itself)
26 native    the card as shipped: power limit 150 W, clock ceiling at the top, firmware alone
27 omni      native + Omni-Compass on top, through two wires (omnicompass/bowl.py): the clock ceiling is the up wire (ho
28 w         high boost may push), the power limit is the down wire (the lid, set just above what the ceiling draws,
29         never under the card's own busy draw). The bowl's reading is the response time as a position between the
30         bare service time (0) and the service line (1); the brain pulls it to the center. The verdict
31         (omnicompass/verdict.py) decides how far the ceiling may go: a step down is allowed only after a paired
32         trial shows it costs each request at most ALLOW of the card's own time on it; where no step passes, the
33         ceiling stays where the firmware has it. Both wires are restored to their snapshot at 90% of the run
34         cap      a fixed power cap set by the operator and left (105 W, 70%), firmware alone under it
35         cap_omni the cap + Omni-Compass on top: the same law, the lid never above the operator's cap

4  """Realm harness: every muscle native, watched and governed; every realm, and the whole tower, as one organism.
5
6  Arms, all on the same seed (the same demand, weather, disturbances):
7      native the plant and its native controller alone
8      watch  the frozen governor reads the plant every period and writes nothing; must equal native exactly
9      omni    the frozen governor holds the muscle's one knob; at 90% of the run it is killed, the knob returns to the
10             native controller, and the harness checks that it did
11
12  The governor is omnicompass.adapter.Governor, unchanged (the engine with u = 0, the stack law, the kill switch).
13
14  Single muscle: one plant, one governor reading that plant.
15  Organism: all the plants of a realm (or all 656) on one 15 s clock, coupled: the electrical power of compute, motion
16  and process plants is heat in the realm's thermal zones; the organism's load swing is load on its storage sites; the
17  zones' temperature is the ambient every other plant reports. One governor reads the organism's aggregate and its one
18  directive sets every muscle's knob.
19
20  Primary outcome per seed: work per energy, omni against native: (work_omni / work_native) / (energy_omni /
21  energy_native) - 1. For an organism, work is the mean over its plants of work_omni / work_native (their work units
22  differ) and energy is total joules. Guardrails: work not lower by more than 1%; the share of periods in violation not
23  higher by more than 1 percentage point. Labels by rule (label()).

4  """Realm plants: the machines the 656 muscles act on (evidence class S: declared models, not meters).
5
6  Five plant models. Each one carries its own native controller and runs correctly with no Omni at all:
7
8  compute_pool    servers, nodes, GPUs, robots, radio cells or workers serving a request stream; native: the Kubernetes
9                  HPA rule (desired = ceil(n * utilisation / target), 10% tolerance, scale-down stabilisation window,
10                 start-up delay), a fixed admission limit, full clock
11  thermal_zone    a data hall or building zone cooled by staged units; native: PI on a fixed setpoint, units staged to
12                 the load, chiller COP from supply and outdoor temperature
13  energy_storage  a site with load, solar and a battery behind a grid connection; native: self-consumption above a
14                 fixed reserve
15  motion_axis     a joint, flight axis, spacecraft axis or vehicle doing point-to-point moves from a task queue;
16                 native: PID with feedforward at full speed, motor heating and derating
17  process_loop    a first-order process with dead time (level, pressure, chamber temperature, feeder voltage);
18                 native: PI on a fixed setpoint, pump or heater power from the actuator
19
20  A muscle is one knob of one plant. Omni may hold that knob and only that one; the native controller keeps the rest.
21  Omni commands a knob the way the shipped controller commands its organs (omni_controller/controller.py,
22  omni_controller/muscles.py), through the nervous system's authority (omnicompass/nervous_system.py, from_governor):
23
24  expand          adding capacity, performance or protection is always allowed (except during a security hold)
25  contract        giving any of it back (fewer machines, a lower speed or power limit, a warmer setpoint, a lower reserve
26                 of protection) only while the organ has contraction authority (calm >= the organ's threshold, senses live)
27                 and the plant's service has been clean for the last three decisions (the SLO reflex); continuous organs
28                 shed at most the calm fraction of their surplus per decision, discrete organs one unit, through a release
29                 gate (nothing waiting, and after the release the rest runs at or under the engine's utilisation target)
30  fail up         while service is breached, the knob returns to the native controller at once
31  pacing          admission muscles are batch pacing (the live batch_pace muscle): one muscle's work suspended per decision
32                 while power stress >= 0.95 or heat >= 0.96 or the nervous system calls a pause; one resumed per decision
33                 once power stress <= 0.8 and heat < 0.90 (realms/harness.py, pace)
34
35  By plant and knob:
36  compute_pool    replicas and HPA-type knobs: the HPA target written as min(rho*, the operator's target), never tighter,
37                 held for one autoscaler window (the live controller's rule); machine pools (Cluster Autoscaler native):
38                 the node release gate; power: the GPU or CPU-frequency envelope, never under the work's draw plus 30%,
39                 and never on a request-served pool (the live controller: throttling it saves no energy, only adds
40                 wait); admission: batch pacing of pausable work only (request traffic is never paused)
41  thermal_zone    setpoint: the live cooling law (warm while cool, cold as heat rises, inside [stress, stress + band x
42                 calm]); units: the release gate; power: the site power envelope above the load plus 10%; admission:
43                 paced, the migratable 10% is shed
44  energy_storage  reserve by power stress (released under stress, held when calm only with authority); peak-shave
45                 ceiling at rho* of the connection (expand only); battery power: the site power envelope; admission:
46                 paced, the flexible share is deferred; resumed, it is caught up
47  motion_axis     speed: up at once to demand, down by the calm share of the surplus; effort: the power envelope;
48                 admission: paced, no new move starts
49  process_loop    setpoint: toward the efficient end of its band by the calm share; actuator range: as motion speed;
50                 power: the site power envelope above use plus 10%; admission: paced, 10% is shed
51
52  Every disturbance trace is drawn from the seed when the plant is built, so all arms of a seed see the same ones.
53  Meters (work, energy_j, viol, steps) are kept by the plant from its own state; Omni never supplies them.

4  """Parameter sets of the realm plants, fixed before any confirmation run (docs/REALMS_PREREGISTRATION.md).
5
6  One set per preset named in realms/catalog.csv. Each muscle runs its family's set at its own size: the work scale
7  (request rate, IT load, site load, process demand) is multiplied by 0.6 to 1.4, drawn from the muscle id, so the 16
8  muscles of a family are 16 differently sized plants. Values are round engineering figures for the class of machine,
9  not measurements of any product.
10
11  Two clocks:
12      single      each plant on its own natural decision period and horizon (STEPS_SINGLE)
13      organism    every plant on one shared 15 s decision clock for 240 steps (one hour), so they can be coupled

4  """Work served under the closed-loop load (deploy/kind/loadgen.yaml), estimated per repetition.
5
6  python3 tools/closed_loop_estimate.py DIR          # DIR holds bench-<arm>-<rep>/ with latency.csv, capture.csv, load_sch
   edule.log
7
8  Each generator sends 20 requests one after another, each waiting for its answer, then sleeps RANDOM % 3 s (mean 1 s).
9  A generator's cycle is therefore 20 R + 1 s, R the mean response time, and it serves 20 / (20 R + 1) requests a second.
10 The requests of an arm are that rate times the generator-seconds of the load schedule. R is the mean response time of
11 the probe's successful requests in the same arm (the same service the generators call). The generators do not count
12 their requests, so this is an estimate; an open-loop load (LOADGEN=open) or a server-side count replaces it.
13 Prints, for Omni-Compass on top against native, paired over repetitions: requests, CPU used, CPU per request.

4  """The speed lock's baseline: response time without Omni, as a function of arrival rate.
5
6  python3 tools/gpu_baseline.py baseline.json native-run-1/latency.csv [native-run-2/latency.csv ...]
7
8  Each file is a run without Omni (elapsed_seconds,latency_ms,ok, as tools/gpu_workload.py writes). Windows of
9  --window-s seconds, one every --every-s, give (arrival rate, mean, p95, p99); windows are grouped by rate in bins of
10 --bin requests per second and each bin keeps the median of its windows. omni_controller/gpu_governor.py
11 --baseline-file reads the result with the same window, so the lock compares like with like. Use runs that are not the
12 ones the comparison is made on (other seeds), so the lock is not tuned on the arms it is judged by.

4  """The GPU test without a GPU: Omni-Compass's own GPU governor (omni_controller/gpu_governor.py, its command-line default)
5  against a modelled NVIDIA card, in virtual time. A preview, not evidence: every energy number here comes from the model
6  below, not from a meter. The hardware answer is scripts/gpu_paired.sh on a real card.
7
8  python3 tools/gpu_physics_sim.py                                # 10 paired repetitions, both card models, table to stdout
9  python3 tools/gpu_physics_sim.py --reps 5 --out results/gpu/sim --gov "--min-share 0 --util-gate 0" # other settings
10
11 The card (an assumption, stated):
12 idle draw      40 W while no request is being served
13 busy draw      P(s) = 80 + 220 s^gamma W at speed s (1 = full clock); 300 W at full clock, the start limit
14 power limit L  below 300 W the card slows to the speed where P(s) = L, as real cards do by lowering clocks
15 heat          first order toward 30 C + 0.12 C/W x draw, time constant 20 s
16 gamma is how much the top of the clock range costs: 3 when voltage falls with clock (good for capping), 1.5 when the
17 card already sits near its voltage floor (hard for capping). Both are run; a real card lies somewhere between.
18
19 The workload is tools/gpu_workload.py's: Poisson arrivals at 30, 60, 80, 30, 60, 30% of full-speed capacity, seed
20 20260928 + repetition, one server first come first served, 50 ms per request at full speed, 600 s plus 30 s drain; the
21 response-time target is ten service times (500 ms), as scripts/gpu_paired.sh sets it. The governor decides at its own
22 interval (default 2 s) from the modelled card's nvidia-smi readings and the response-time file, exactly as on hardware.

4  """Speed won on the CPU, spent on the GPU: a request served by a CPU stage and then a GPU stage, with Omni-Compass's
5  speed lock (omni_controller/gpu_governor.py --baseline-file) on the GPU. A preview on a model, not evidence.
6
7  python3 tools/gpu_pipeline_sim.py                                # 10 paired repetitions, both card models
8  python3 tools/gpu_pipeline_sim.py --cpu-ms 10 --out results/gpu/sim/pipeline
9
10 Each request needs --cpu-ms of CPU work on one core (preparing the input) and then the GPU (tools/gpu_physics_sim.py's
11 card and workload: 50 ms at full clock, Poisson arrivals at 30/60/80/30/60/30% of GPU capacity). The serving pod's
12 CPU limit is enforced as Linux does it (CFS bandwidth): a quota of limit x 100 ms of CPU time per 100 ms period; the
13 pod's work runs at a full core until the period's quota is spent, then waits for the next period. The operator's
14 --native-limit (0.5 core: 50 ms per 100 ms) throttles bursts; Omni's conveyance (omni_controller/muscles.py convey:
15 the machine's idle CPU to the serving pods) raises the limit to --conveyed-limit (1 core: never throttled for one
16 thread). Both stages are first come first served queues.
17
18 Arms, paired on the same arrivals:
19     native operator's CPU limit, GPU at its start limit (no Omni)
20     speed CPU conveyed, GPU at its start limit: the speed the CPU muscle wins, handed to the customer
21     lock CPU conveyed, GPU under the speed lock: the speed won is spent on GPU watts, keeping every gauge (mean,
22     p95, p99) at least --speed-gain faster than native
23 The lock's baseline comes from native runs on other seeds (tools/gpu_baseline.py), never from the arms judged.
24 CPU work is the same core-seconds in every arm (conveyance moves no work, it removes waiting); only GPU energy differs.

4  """The GPU bench table (scripts/gpu_paired.sh): native / watch (Omni runs, writes nothing) / omni (Omni writes power li
   mits).
5
6  Every energy number comes from the device: joules = the time integral of nvidia-smi power.draw over the measured window
7  (trapezoid rule on its own sample timestamps), summed over the measured GPUs; the CPU package joules come from RAPL
8  energy counters when the machine has them. Nothing here is a model.
9
10 Per repetition, per arm: energy, joules per served request, mean power, peak and mean temperature, served and not
11 served requests, response time (mean, 95th, 99th percentile), power-limit writes. Across repetitions: for watch and omni
12 against native, the paired mean difference with a t-based 95% interval. A difference is proven when that interval
13 excludes zero; otherwise the table says not proven.
14
15 Three contrasts, each paired by repetition: observation = watch - native (does Omni's presence alone move the plant),
16 authority = omni - watch (what granting Omni the write adds), total = omni - native (the preregistered comparison).
17 Three receipts, kept apart: A the governor's decisions (audit.jsonl), B its actuator records (requested, return code,
18 read-back, enforced limit, delay), C the bench's own nvidia-smi samples and the workload's requests. From A and B the
19 table also reports actuator fidelity, control effort, and how well the engine's six-state projection matches what the
20 telemetry shows next (the intertwining residual and directional accuracy), defined in docs/GPU_PREREGISTRATION.md.
21 The result label is chosen by rule (label()), never by hand. A meter that was not fitted prints UNAVAILABLE.
22
23 The run is INVALID (exit 2) when: a native or watch arm saw a power limit (or enforced limit) other than the one read a
   t
24 start, the watch arm executed a write, an arm ended with a limit that differs from the start (the kill switch did not
25 restore), a governor exited nonzero (a refused write, a refused start), a write was refused, Omni's frozen files
26 changed, a confirmation ran on uncommitted code, or smoke and confirmation repetitions were mixed.
27 Usage: python tools/gpu_reps.py RUN_DIR (RUN_DIR holds rep-<n>/<arm>/) -> RUN_DIR/GPU_REPS.md, RUN_DIR/GPU_REPS.js

5  """The wire check: before any test, prove both of the card's wires are connected the right way round.
6
7  Run as root on the machine with the card (scripts/gpu_rented_run.sh runs it first, and stops if it fails):
8
9      sudo python3 tools/gpu_wire_check.py [--gpu 0] [--smi nvidia-smi]
10
11  1 read          every meter answers: watts, temperature, utilization, power limit, clock, top clock
12  2 snapshot      the starting power limit, read once
13  3 up wire       with the card busy, read the clock it runs at on its own (its power limit may already hold it below
14                  the top), lock the ceiling at 60% of that: the clock must come down under it; reset it: the clock
15                  must come back above it (the ceiling is followed, in the right direction)
16  4 down wire     set the power limit lower: the card must report it; set it back: the card must report the start
17  5 restore       clocks reset and the start limit, read back
18  6 stop          the two-wire governor, stopped by its stop signal, hands both wires back
19  7 other writer  someone else moves the limit while the governor runs: it must stop writing, leave that value alone and
20                  exit 5
21  Each step prints PASS or FAIL with the wire, the step and what the card said; the first failure stops the check (exit 1
22  )
23  and leaves the card at its start values. Exit 0: wired right.

4  """The pinned GPU workload for scripts/gpu_paired.sh: a fixed stream of inference-like requests served by one GPU.
5
6  Each request is --iters passes of one of two kernels on the GPU (synchronised, so its time is the GPU's time):
7  --kind matmul    fp16 matrix products of size --n x --n: compute-bound, its speed follows the core clock
8  --kind decode    fp16 matrix times one vector, the weights --n x --n x --layers (by default 8192 x 8192 x 8, 1 GiB):
9                  each pass streams every weight from the card's memory once, as AI token generation does at batch one,
10                  so its speed follows the memory, not the core clock
11  Requests arrive open-loop on a schedule fixed by --seed: Poisson arrivals whose rate steps through --phases, each phase
12  a
13  share of the GPU's own capacity measured by `calibrate` at full power before any arm runs. Every arm therefore receives
14  exactly the same requests at exactly the same moments; what differs is only how the GPU is governed.
15
16  calibrate times --calib requests back to back at the current (start) power limit and writes calib.json:
17  iters (chosen so one request takes about --target-ms), service_ms, and every setting below
18  run       serves the schedule for --duration seconds, then --drain seconds for requests still queued, and writes
19  latency.csv (elapsed_seconds, latency_ms, ok, service_ms) live, one row per finished request; service_ms
20             is the card's own time on the request (start to done, the wait in the queue left out)
21  requests.csv (arrival_s, start_s, done_s, latency_ms, ok)
22  summary.json (requests, served, not served, t0_epoch: the wall clock at time 0, the settings)
23  Any other workload (vLLM, TensorRT-LLM, an MLPerf inference harness) plugs into the bench through WORKLOAD_CMD
24  (scripts/gpu_paired.sh) by writing the same three files; tools/gpu_reps.py checks them.
25  A request still queued when the drain ends is not served (ok = 0).
26  --sim replaces the GPU by a sleep of service_ms (for the harness's own tests on machines without a GPU).

5  """Real AI serving for the GPU bench: a language model served by vLLM (OpenAI-compatible server on this machine), asked
6  the same seeded stream of prompts in every arm, so the card's firmware alone and the firmware with Omni-Compass on top
7  get exactly the same requests at exactly the same moments.
8
9  Each request asks for exactly --tokens new tokens (ignore_eos), so every request is the same amount of work. It writes
10 the three files the bench reads (scripts/gpu_paired.sh, WORKLOAD_CMD):
11   latency.csv   elapsed_seconds, latency_ms, ok, service_ms   one row per finished request (service_ms: the request's
12                  time in the server, which on a batching server is its time to finish)
13   requests.csv  arrival_s, start_s, done_s, latency_ms, ok
14   summary.json  requests, served, not served, t0_epoch, tokens per request, the model
15
16   calibrate    time --calib requests one at a time; writes calib.json (service_ms: the median, the bench's response line
17                  is ten times it)
18   run          serve the schedule for --duration seconds (Poisson arrivals at --rate per second), then --drain seconds
19
20 Tokens per second = requests served x --tokens / duration; the bench's work per energy is requests per kJ, so tokens
21 per kJ is that times --tokens.

4  """The mechanism's identity: M = (F, Theta, C, h, G, M_act, dt, A), one fingerprint per engine configuration.
5
6  python3 tools/mechanism_identity.py          # write results/MECHANISM_IDENTITY.json
7  python3 tools/mechanism_identity.py --check  # compare the code with the recorded identity (verify.py runs this)
8  python3 tools/mechanism_identity.py --id     # the canonical mechanism id of the code as it stands (the GPU bench re
9  cords it)
10 Each component is fingerprinted (SHA-256) from the source text of the functions that compute it, and Theta from the
11 values of every constant and parameter. The mechanism id is the SHA-256 of the eight component fingerprints in order,
12 so it changes exactly when a component changes, and changes in unrelated code (reports, docs) leave it alone.
13
14 F      state law          dx/dt = F(x, d, u; Theta): derivatives (+ v_eff, s_flow), per configuration
15 Theta  parameters        Params defaults, PARAMETER_RANGES, KP, U_AUTHORITY, steps, windows, ASSIMILATION
16 C      internal controller u = clip(-f_U + KP (sigma - U), +-U_AUTHORITY), per configuration
17 h      observation map    observe_vector, assimilate (omnicompass/adapters.py)
18 G      authority law      Governor.step, AllocationLaw, mode Law (omnicompass/adapters.py)
19 M_act  authority -> actuator GPU power limit (omni_controller/gpu_governor.py: shield_limit, busy_gate,
20      lock_decide, GpuGovernor.set_limit, GpuGovernor.step); Kubernetes (omni_controller/
21      muscles.py)
22 dt      execution contract rk4_step, macro_step (u computed before each RK4 micro step, held through its four
23      stages), MACRO_DT, MICRO_STEPS; the GPU decision interval
24 A      admissibility / shield omnicompass/shield.py (violations, enforce, ShieldLimits), shield_limit
25 Also records the frozen 500-fixture comparison of the two configurations (benchmarks/core_evidence.py population,
26 seed 223387268): executable both, not interchangeable. No new population is drawn.

5  """The master switch for the whole Omni-Compass harness (omnicompass/master.py).
6
7  python3 tools/omni_switch.py off [--reason TEXT] [--wait 60]
8      turns every Omni-Compass governor on this machine off at once: sets the switch, signals every running governor
9      (SIGTERM), and waits until each has put every setting back and exited. Exit 0 when all are gone, 1 if any is
10     still running after --wait seconds (its name and pid are printed; the switch stays OFF).
11  python3 tools/omni_switch.py on
12     allows governors to be started again (nothing restarts by itself)
13  python3 tools/omni_switch.py status
14     OFF or ON, every governor running, and any that died without handing back
15  python3 tools/omni_switch.py watchdog [--stale 60] [--every 10] [--once]
16     puts back every setting of any governor that died or hung without doing it itself (its recorded restore commands)
17
18     stopping a hung one first; run it as its own service next to the governors
19  OMNI_MASTER_OFF sets the switch file (default /tmp/omni-compass/OFF); every governor and this tool must agree on it.

4  """OmniCompass Runtime Benchmark Protocol (benchmark_protocol.docx), stage 1, on the fleet plant (fleet/sim_slo.py).
5
6  Same scenarios, same faults, every architecture:
7      A each platform alone      k8s_hpa70_ca, openshift, gke_optimize, aks_nap, turbonomic, cast_ai, spot_ocean
8      B Omni-Compass on top of it  omniB:<platform> with the frozen per-platform settings (tuning/B_SETTINGS_PER_PLATFORM.
   json)
9      C Omni-Compass alone      C-hpa: the held-out C league pick (HPA kept); C-strict: the closure law, HPA replaced
10     (settings: tuning/CLOSURE_SEARCH2_DEV.json, else CLOSURE_SEARCH_DEV.json, else defaults
   )
11
12 Stress levels 1-5 (protocol section 6). Level L injects L fault events, times drawn uniformly in [120, 1200) ticks, eac
   h
13 one of (drawn with the seed, identical for every arm):
14     node_crash      L x 10% of the cluster's running machines die at once (at least one)
15     load_spike      every workload in the cluster: demand x (1 + 0.5 L) for 20-80 ticks      (queue overload, scaling)
16     service_crash   L x 20% of the cluster's services lose half their pods (crash loop, restart churn) and queue
17                     two ticks of demand as backlog
18     cpu_pressure    a noisy neighbour: extra demand of L x 8% of the cluster's allocatable cores for 40-160 ticks,
19                     spread over the workloads
20 Admissible basin, per tick (declared before any run): worst response time <= 1000 ms (10 x service time),
21 queue ratio < 0.28, pending pods <= 5% of requested, site power <= 1.02 x limit, thermal < 0.96.
22 Gauges (protocol section 7):
23     conveyed        every fault recovered within 20 min (80 ticks) AND all clusters in the basin for the last 10 min
24     recovery time    from a fault to the first tick that starts 2 min (8 ticks) in the basin; unrecovered = to the end
25     failure persist. minutes outside the basin
26     pages           out-of-basin episodes lasting 5 min or longer (the Prometheus `for: 5m` rule): each one calls a
27                     human (the protocol's human intervention count; nobody intervenes in the simulation)
28     max error / CPU / queue / latency, timeouts (demand share with response > 2 s), work completed, energy
29 Usage: python tools/protocol_bench.py [runs_per_level=100] -> results/protocol/{raw_results.csv, summary_results.csv
   ,
   PROTOCOL_SUMMARY.json}
30

4  """Build realms/catalog.csv: the 656-row muscle tower, each row given its realm, its plant, and the knob Omni may hold.
5
6  python3 tools/realms_catalog.py CANONICAL_656_TOWER.csv
7
8  The tower itself (muscle id, family, name) comes unchanged from the XPASS package's canonical 656 list. This tool adds
9  four columns by the fixed rules below; the result is committed as data, so every row can be read and contested:
10
11  realm      the muscle's home realm, by family
12  realms     every realm whose organism includes it: its home realm, and all four for the shared spine (SPINE below):
13             the infrastructure every real stack runs on (Kubernetes, machines, GPUs and CPUs, network, storage,
14             observability, security, cooling, electrical distribution)
15  template   the plant model the family runs on (realms/plants.py)
16  preset     the family's parameter set for that plant (realms/presets.py)
17  knob       the one knob Omni may hold for this muscle: capacity, setpoint, power or admission, from the muscle's name
18             (first matching rule of its template, else capacity)

4  """The release's one identity: RELEASE_MANIFEST.json.
5
6  python3 tools/release_manifest.py          # write the manifest, run verify.py --quick, record its receipt
7  python3 tools/release_manifest.py --check  # compare the files with the manifest (verify.py runs this)
8
9  The manifest names the commit it was written at and fingerprints (SHA-256) everything that identifies the release: the
10 canonical engine and the reference engine, the C++ twins (through the seal), the GPU protocol, the live evidence
11 (execution commit, run id and raw-file digests of sets 20 and 21), the canonical engine declaration, and the receipt
12 of the verification run made when it was written. One object, so nobody has to reconstruct provenance from history.

5  """The whole stacks with the real card inside: one harness, one engine, one set of receipts.
6
7  Each of six organisms (the four realms, the four stacked with every duplicate kept, 1,226, and the whole tower of 656,
8  realms/catalog.csv) runs on one clock as in the realm
9  harness, and the real GPU on this machine is wired into it as one more muscle of its NVIDIA GPU family (a spine family,
10 so the card sits in every organism): the card serves the pinned request stream (tools/gpu_workload.py), its own
11 power.draw is heat in the organism's thermal zones and load on its storage sites, and its meter and its requests are
12 counted in the organism's receipt.
13
14 Arms, the same organism, the same seed, the same request stream:
15     native the stacks' own controllers and the card's own firmware, no Omni
16     omni    one engine on everything: the bowl law (omnicompass/bowl.py) on every simulated muscle (realms/bowl_arm.py)
17            and on the card's two wires (omni_controller/gpu_bowl.py); at 90% of the arm every knob and both wires are
18            handed back, and the harness checks they were
19
20 Sizes (--scales, default 1,10,100,1000): each organism is run as 1, 10, 100 and 1,000 copies governed together on one
21 clock (1,000 copies of the whole tower is 656,000 muscles), with the one real card inside as one more muscle. Each size
22 runs its own number of paired repetitions (--reps-by-scale, default 3,3,2,1).
23
24 Each organism step is --step-s seconds of wall clock (240 steps: 8 minutes at 2 s). A size whose simulated step takes
25 longer than that gets a longer step, measured on this machine before the run (1.5 times the time the simulation needs
26 per muscle, times its muscles); the card's request stream runs for the same 240 steps, so the card and the stacks stay
27 on one clock. Every size's step is in the receipt. The simulated plants are evidence class S (models); the card's
28 energy and requests are class P (its own meter). The receipt keeps them apart and also adds them up.
29
30 python3 tools/run_hil.py --out results/hil/run-STAMP [--scales 1,10,100,1000] [--reps-by-scale 3,3,2,1] [--sim]

5  # One paired repetition on a real, billed Azure Kubernetes Service cluster (.github/workflows/aks-metered.yml): every
6  # arm back to back, each on a fresh cluster built the same way, in an order rotated by repetition, the same as
7  # scripts/kind_paired.sh on kind. Each cluster:
8  #   system pool 1 machine, tainted CriticalAddonsOnly=true:NoSchedule (AKS's add-ons and the load generator; never
9  #   measured, never governed: kind's control plane)
10 #   work pool   agentpool=work, starts at AKS_MAX_NODES machines, under Azure's own cluster autoscaler (min 1, max
11 #               AKS_MAX_NODES), which deletes a machine once it is empty. Native: the autoscaler alone. Omni on top: t
12 #               he
13 #               same autoscaler, with Omni-Compass idling the machines it gives back, which the autoscaler then delete
14 #               s
15 # The bill (scripts/kind_bench.sh, PLATFORM=aks) counts every work machine that exists, every 15 s. Each cluster is
16 # deleted when its arm ends, before the next is made, so nothing keeps billing and the subscription's core quota holds.

5  # The 8-GPU result, one command on a rented machine with several NVIDIA cards (docs/GPU_RUN_GUIDE.md, section D):
6  #
7  #   sudo bash scripts/gpu_8card.sh           the whole design, about 17 to 18 hours
8  #   sudo POOLED=1 bash scripts/gpu_8card.sh  every stage, repetitions pooled across the cards, about 9 to 10 hours
9  #   sudo FAST=1 bash scripts/gpu_8card.sh    the short design, about 3.5 hours (what only a full server shows)
10 #
11 # Every card on the machine runs the whole card test at the same time (scripts/gpu_rented_run.sh with GPU=<card>): its
12 # own wire check, envelope, smoke, the two preregistered confirmations (compute and AI token generation) and the
13 # operator's power cap underneath, each card its own firmware alone against the firmware with Omni-Compass on top, on
14 # the same committed code. The cards share one machine, its power supply, its cooling and its neighbours' heat, as in a
15 # real server. Each card starts its arm rotation one step later than the card before it, so at any moment some cards
16 # run native and some run Omni-Compass, and no arm always meets the same neighbours.
17 # Then, with every card idle again: the GPU fault drill once, on card 0 (the master switch stops every governor on the
18 # machine, so it never runs while the cards measure). Then one pooled table per workload: every repetition of every
19 # card, paired within its own card (tools/gpu_reps.py), and each card's own table beside it.
20 #
21 # Last, the whole server as one: a language model served across every card at once (scripts/gpu_vllm.sh with GPU=all
22 # cards: vLLM tensor parallel, one Omni-Compass governor per card, the server's total GPU energy), SKIP_LLM=1 skips it.
23 # Then the whole stacks with a real card inside: the six organisms at 1x, 10x, 100x and 1,000x copies, full
24 # repetitions, each organism on its own card at the same time (SKIP_HIL=1 skips it; HIL_ARGS passes options through).
25 # CARDS (default: every card nvidia-smi lists), SKIP_DECODE=1, SKIP_CAP=1, SKIP_DRILL=1 as in gpu_rented_run.sh.

5  # One command on a machine with an NVIDIA GPU: native vs Omni-Compass watching vs Omni-Compass governing the GPU's
6  # power limit, measured by the device itself. Run as root (nvidia-smi -pl needs it). Needs python3 with torch (CUDA).
7  #
8  #   sudo bash scripts/gpu_paired.sh                # 5 repetitions x 3 arms x 10 min (about 3 hours with idle gaps)
9  #   sudo REPS=5 DURATION=300 bash scripts/gpu_paired.sh  # shorter arms
10 #
11 # Each repetition runs the three arms back to back, order rotated. Each arm: COOLDOWN s idle, then the pinned workload
12 # (tools/gpu_workload.py: the same seeded stream of fp16 matrix-product requests every arm) for DURATION s plus DRAIN s
13 #
14 # with nvidia-smi sampling power.draw, temperature and power.limit every SAMPLE_MS ms, and RAPL CPU package energy
15 # counters read at both ends where the machine has them.
16 # native no Omni process
17 # watch Omni runs and decides, and is forbidden to write (the control: any write fails the run)
18 # omni Omni holds the card's two wires, clock ceiling and power limit (omni_controller/gpu_bowl.py --mode cap;
19 #   OMNI_ENGINE=one_wire runs the earlier power-limit-only governor, omni_controller/gpu_governor.py)
20 # Three receipts, kept apart: A the governor's audit.jsonl (telemetry, six-state reading, command, shield), B its
21 # actuator records (requested, return code, read-back, enforced limit, delay), C the bench's own nvidia-smi sampling
22 # and the workload's requests.csv (Omni never supplies its own outcome). Refused unless power management is Enabled.
23 # The power limit is read once at the start (the snapshot). Every arm must begin and end at it; the kill switch restore
24 # it after the omni arm. The table (tools/gpu_reps.py) prints each gauge with its 95% interval; an interval that includ
25 # es
26 # zero says not proven. Output: results/gpu/run-<UTC time>/ with every raw file and SHA256SUMS.txt.

5  # The whole GPU test on a rented NVIDIA machine, one command (docs/GPU_RUN_GUIDE.md, section C):
6  #
7  #   sudo bash scripts/gpu_rented_run.sh
8  #
9  # 1. checks the machine (NVIDIA GPU, root, PyTorch with CUDA, power management Enabled), then the wire check
10 #   (tools/gpu_wire_check.py: both of the card's wires follow, read back and go home);
11 # 2. declares the envelope before any trial (docs/GPU_PREREGISTRATION.md, amendment 3): lowest watts =
12 #   max(device minimum, 70% of the limit read now), unless ENVELOPE=file.json is given;
13 # 3. smoke: 3 repetitions x 3 arms x 180 s (about 40 minutes). It checks the wiring on real hardware. It never counts;
14 # 4. if smoke is valid: the preregistered confirmation, 10 repetitions x 3 arms x 600 s (about 6 hours), on the same
15 #   committed code (STOP_AFTER_SMOKE=1 stops after step 3), on the pinned compute-bound workload (matrix products);
16 # 5. the second preregistered confirmation, the same 10 x 3 x 600 s on AI token generation (the decode workload:
17 #   every weight streamed from memory once per pass, batch one), about 6 hours more (SKIP_DECODE=1 skips it). Each
18 #   workload is its own result, never pooled;
19 # 6. an operator's power cap underneath (70% of the default limit): the cap alone vs the cap with Omni-Compass on top,
20 #   at the usual load and fully loaded (more work from the same watts), 5 repetitions each, 300 s per arm, about 3 hou
rs
21 #   (SKIP_CAP=1);
22 # 7. the GPU fault drill, about 10 minutes: the governor killed outright, the master switch pulled, the response feed
23 #   blind (SKIP_DRILL=1); everything so far is then packed;
24 # 8. the whole stacks with this card inside (tools/run_hil.py): the four realms, the four stacked with duplicates
25 #   (1,226) and the whole tower (656), each as 1, 10, 100 and 1,000 copies on one clock with the card inside, native
26 #   and Omni (repetitions 3, 3, 2, 1 by size; HIL_SCALES and HIL_REPS_BY_SCALE change them; SKIP_HIL=1 skips it);
27 # 9. real AI serving last: a language model served by vLLM, installed in its own environment, 5 repetitions x 3 arms x
28 #   300 s; if it cannot install or start, the stage says so and nothing before it is affected (SKIP_LLM=1);
29 # 10. packs every result folder into one file to send back, and prints the label each table chose by rule.

5  # One arm of the native-vs-Omni benchmark on the six-worker kind cluster (deploy/kind/cluster-full.yaml).
6  # Both arms are wired identically: same cluster, add-ons, workload, HPA (target 50), load schedule, capture and
7  # power model. The only difference:
8  #   ARM=native   Omni-Compass is not started at all. Kubernetes (HPA, scheduler) runs alone on all workers.
9  #   ARM=omni     Omni-Compass runs in nodepool mode with every live muscle: HPA target, node pool (prefer-not idle mark,
10 #                first-to-go order),
11 #                power cap (CPU limit of php-apache, enforced by the kernel), heat (harness law on live power), security
12 #                (ConfigMap hold), rollout guard, and the latency afferent: 95th-percentile response time over SLO_MS
13 #                (declared before the run, default 500 ms) enters the engine as queue pressure. The power cap never goes
14 #                below pod usage x 1.3. Parked workers stay powered and Ready at their idle floor (STANDBY_W =
15 #                park_frac x idle, never off).
16 #   ARM=watch    Omni-Compass runs exactly as in ARM=omni (same process, same reads, same senses, same decisions) with
17 #                --dry-run: every write is logged, none is executed. Any difference from native in this arm is the cost
18 #                of
19 #                Omni-Compass being there (its CPU on the shared runner, its API reads) plus run-to-run noise, never a
20 #                decision. The run fails if one write reached the cluster.
21 # The controller runs at the lowest CPU priority (nice 19) in every Omni arm: on a real cluster it runs on its own node
22 # here all seven kind nodes share one 4-core runner with the service being measured.
23 # Both arms: a real response-time probe times HTTP requests to php-apache every 5 s (latency.csv).
24 # Load schedule: the load-generator replica count steps through LOAD_STEPS, each step DURATION/steps seconds,
25 # identical in both arms. Results in $OUT_DIR: capture.csv (every 15 s), nodes timeline, Omni audit (omni arm).
26 # Evidence discipline (adopted from the ChatGPT-built harness, extended to every muscle): pinned, SHA-256-checked
27 # metrics-server; preflight record of tool versions; clean-cluster check; Omni-Compass runs as a least-privilege servic
28 # account (deploy/kind/rbac-omni.yaml) with `kubectl auth can-i` receipts for what it can and cannot do; the run fails
29 # if
30 # Omni made no write or if the kill switch leaves any record behind; SHA256SUMS.txt fingerprints every output file.

4  # Serving path for the live benchmark (applied in BOTH arms by scripts/kind_bench.sh).
5  # 1. A NodePort in front of php-apache. The response-time probe reaches the app the way a client does: through the
6  #    Service, via kube-proxy on the control-plane node (never parked), load-balanced across every ready endpoint.
7  #    A tunnel to one pod (kubectl port-forward) would hang when a drain moves that pod and count every later request as
8  #    failed in the draining arm only; the Service path measures what a real client sees.
9  # 2. A PodDisruptionBudget, the standard Kubernetes guard for voluntary disruption: a drain may never evict the last
10 #    ready replica. Kubernetes alone never evicts in this benchmark, so the budget binds only when nodes are drained.

4  """The bowl law in the live Kubernetes controller (--law bowl), against the fake kubectl (tests/fake_cluster/kubectl).
5
6  calm      p95 far under the SLO: the bowl pulls down, the HPA target never rises above the operator's (never tighter
7            than native), and the node pool gives one machine back per decision through the release gate
8  hot       p95 past the 0.95 wall: fail up, the HPA target goes to the bottom of its cover (60% of the operator's) at
9            once and the node pool asks for one machine more
10 blind     no live probe samples: read as past the wall, same as hot
11 demand    calm again while the demand still grows: the extra pods stay; the operator's target returns once the
12            demand has stopped growing for one autoscaler window (no remove-then-restart)
13 sensed     two services, the probe measuring one: only its HPA moves; the neighbour's stays the operator's
14 restore    the kill switch returns every HPA target to the operator's and removes every record
15 engine     the six-state engine still runs every decision (E and U in the audit) and the decision names the bowl law
16 """

4  """The GPU bench (scripts/gpu_paired.sh, omni_controller/gpu_governor.py, tools/gpu_reps.py) against a stand-in nvidia-
   smi
5  (tests/fake_gpu/nvidia-smi): the governor's contract and the bench's validity checks, without a GPU.
6
7  Governor contract: the start limit is read and recorded before any write; watch computes and records but executes no
8  write; a written limit is never below draw x 1.3 nor the device minimum, never above the start limit; no second write
9  until the last one reads back; a blind sense returns the start limit; a response-time breach returns the start limit;
10 the kill switch restores the start limit and reads it back.
11 Bench: one command runs native / watch / omni with rotated order and prints the table; a watch arm that writes, or an
12 arm that ends away from the start limit, makes the run INVALID."""

4  """The master switch (omnicompass/master.py, tools/omni_switch.py): one OFF for the whole harness.
5
6  Two governors run at once as their own processes, against the stand-in hardware: the two-wire GPU governor on the fake
7  nvidia-smi, and the Kubernetes controller (bowl law, HPA target mode) on the fake kubectl. Then:
8
9  running  both register themselves; status lists both
10 off      one command turns the whole harness off: both governors put every setting back (the card's start limit and
11          clocks, the operator's HPA target) and exit, within seconds
12 refused  while the switch is OFF, neither governor will start (no authority taken)
13 on       after ON, a governor starts again
14 crash    both governors killed outright (SIGKILL: no chance to hand back) while acting; status names them; the
15          watchdog runs their recorded restore commands: the HPA target back to the operator's and the card's clocks
16          and limit back to the start

4  """Live muscles against the fake kubectrl and fake hardware commands: power cap scales the CPU limit and the kill switch
5  restores it; a security hold blocks any expansion; rollouts pause when change is not permitted, resume when it is, and
6  a
7  stuck rollout is undone when rollback is authorised; batch admits one held job only with headroom and never during a
8  hold; the CPU-frequency and GPU power-limit connectors follow the cap and are restored by the kill switch; the heat sen
9  se
10 follows the harness law and GPU temperature; observe mode writes nothing."""

4  """Property test of the safety shield over a large random and adversarial input space.
5
6  For every generated (action set, state, observation, bounds, limits):
7  P1 the enforced action set violates no invariant I1-I5          violations(enforce(x)) == []
8  P2 enforcement is idempotent                                enforce(enforce(x)) == enforce(x), 0 new hits
9  P3 enforcement never invents an action                      every output action kind was in the input
10 P4 a clean action set passes unchanged with no intervention   violations(x) == [] -> enforce(x) == (x, 0)
11 The generator mixes uniform draws with adversarial corners: node targets far outside the bounds, current node counts
12 outside the bounds, power stress at and beyond the limit, security holds, caps outside [0.65, 1], contradictory sets
13 (expand and tighten together), zero and negative targets. Usage: python tests/test_shield_properties.py [cases]"""

800 PREFACE = """"I wrote this book so that whoever connects Omni-Compass to a running system understands what they are
801 connecting: not only which wire goes where, but why the governor behaves the way it does, where its law comes from,
802 and how to prove on their own system what it does for them.
803
804 The book is in eight parts, and it can be read in two ways.
805
806 | You are | Read |
807 |---|---|
808 | CEO, board member, investor | the Foreword, the Executive Summary, Part One, the Results to Date, and Part Eight |
809 | CTO, architect, head of platform | Parts One to Four, then the eight wiring levels in Part Five, then Part Seven |
810 | The engineer wiring it | everything, in order. Do not skip the wire check or the watch level |
811 | Auditor, diligence team | Part Two (the mathematics), Part Seven (the proof), Appendices C, F and H |
812
813 **Part One, the philosophy and the theory,** sets out the closed circle: a system that is closed, bounded and pulled
814 toward a center cannot run away, and everything it does is a return. **Part Two, the mathematics,** gives the eight
815 equations and the control law that make the circle exact, with the theorem, the declaration and the audits that hold
816 them fixed. **Part Three, the physics,** brings the law into the machine: the bowl, push and pull, the band and its
817 cushions, the physics of a processor, and the two-way nervous system. **Part Four, the body,** lays out the 656
818 muscles, the four realms and the six organisms. **Part Five, the harness and the wiring,** is the universal plug and
819 the step-by-step work of wiring Omni-Compass onto a stack. **Part Six, operating it,** is the OFF switch, the rules
820 and the log. **Part Seven, proving it,** is every rule written before a run and every result after it. **Part Eight**
821 is value, the license, the seal and the history.
822
823 **Conventions.** `Code` is a command, file or switch exactly as typed. "Native" means a system as it runs today,
824 without Omni-Compass. "Muscle" means any machine, service or controller Omni-Compass can read and set. "Knob" or
825 "lever" is one setting on a muscle. "The band" is a knob's or a service reading's safe range. A step that writes to a
826 system is marked **WRITES**. Every result carries its evidence class: T for a theorem, V for verification of the code,
827 S for simulation, L for live software, P for a physical meter.
828
829 Some chapters gather documents that were written as the work went on, each at the moment its result came in. They
830 are kept as they were written, because the record of how a result was reached is part of the proof. Where two
831 chapters give different figures for the same thing, the later run and the State of Play govern.""

123
124 Answers reference the Claims Register (C-numbers) and the Technical Manual.
125
126 ## Engineering
127 **Does the mathematics hold?*** Equations (1) to (8), Propositions 1 to 3 and their proofs are in Manual Chapters 2 and
3. The 500/500 CONVEY/CERT result is a property of the controller (Proposition 3), shown by counterfactuals: the contro
ller aimed at the wrong basin also scores {CORE['wrong_target']['convey5']}/500.
128 **Is Python the same as C++?*** Yes (C1, C2). The verifier also builds a deliberately mutated C++ governor and confirms
the parity test rejects it.
129 **Can every number be reproduced?*** `python verify.py` rebuilds the C++, reruns parity, reruns the 100,000,000-decision
soak and compares it with the recorded result, replays held-out scenarios and checks the pre-registered SHA-256 hashes
(program fingerprints are additionally checked when the Python version matches the recorded one).
130
131 ## Operations
132 **Better than what we run today?*** Compared against a documented-behaviour reference model of Kubernetes autoscaling (H
PA tolerance 0.1, 300 s scale-down stabilization, HPA targets 0.5 to 0.8; simplified Cluster Autoscaler with 10-minute
unnecessary time, 0.5 utilization threshold, 10-minute delay after scale-up): C8 to C12, including where Omni-Compass is w
orse. The reference model is not the upstream controllers (C12b); running the upstream controllers against the same sce
narios is the next baseline step.
133 **On real traffic?*** Not yet. Results use a synthetic stack model. Replay of published production traces and the pilot
protocol are the next evidence steps (C14).
134 **What happens when it is wrong?*** Observe mode changes nothing (C6). The kill switch returns control to the native man
agers at the next interval (omni_kill arm). The shield blocks actions that violate I1 to I5 (C7).
135 **Will it wear hardware?*** Machine start/stop cycles, power-cap travel and thermal travel are measured for every arm (C
12, Manual Chapter 8).
136
137 ## Security
138 **What authority does it hold?*** Capacity, replicas, power caps, rollback authorization and routing, only in AUTOPILOT,
only through the shield.

```

```

139 **Can it expand capacity during a security block? No: invariant I1 is enforced before execution.
140 **Does it replace encryption, identity or policy engines? No. Those components are retained (fleet model, security ro
    le).
141
142 ## Finance
143 **What does it save? Energy per run versus current autoscaling (C8). Fleet-scale figures are modeled (C13); the gover
    nance saving comes from reduced idle and padded capacity, not from removing the decision components' own consumption.
144 **What does it cost to run? C5.
145
146 ## Adoption
147 **How is it introduced without risk? Observe, then shadow on production telemetry, then one control loop at a time un
    der the kill switch (docs/PILOT_PROTOCOL.md).
148
149 ## Referees
150 **Was it tuned on the test data? No. Law, shield and baselines were frozen and fingerprinted before the held-out seed
    s {S1} and {S2} (results/PREREGISTRATION.json).
151 **Where does it fail? Backlog violations against current autoscaling (C11); the engine-dynamics ablation (Manual Chap
    ter 8); open obligations (Manual Chapter 10).
152 """
153 (ROOT / "docs" / "DUE_DILIGENCE.md").write_text(dd)
154
155 pp = """# Pilot Protocol
156
157 ## Phase 0: Simulation evaluation (evaluator's own environment)
158 Run `python verify.py`. Pass criterion: VERIFICATION: PASS.
159
160 ## Phase 1: Shadow (2 to 4 weeks)
161 - Capture: `OUT=capture.csv INTERVAL=15 DURATION=<seconds> POWER_CMD="<site power in watts>" bash fleet/capture/kube_ca
    pture.sh` (read-only).
162 - Replay: `python fleet/capture_replay.py capture.csv --idle-w <W> --dyn-w <W> --site-limit-w <W> --out replay/` gives
    Omni-Compass's recommended node count, power cap and HPA target per decision.
163 - Governor in OBSERVE on production telemetry read directly from nodes (kubelet/cAdvisor metrics, power meters, queue d
    epth).
164 - No write credentials are issued.
165 - Logged per interval: directive, native actions taken, and the observed outcome.
166 - Pass criteria, agreed before start: logged directives never violate I1 to I5; counterfactual analysis on at least N r
    ecorded incidents shows the directive would have reduced time-to-recovery or energy without a backlog increase beyond a
    n agreed bound.
167
168 ## Phase 2: Guarded control, one loop at a time (4 to 8 weeks)
169 Order: power capping; node count (Cluster Autoscaler set to observe); replica count (HPA set to observe).
170 - Each loop is handed over separately, with the kill switch tested at handover and at exit.
171 - Pass criteria per loop, fixed in advance: SLO attainment not worse than the preceding shadow baseline at the agreed c
    onfidence level; zero shield invariant violations; energy per unit of completed work reported with confidence intervals
    .
172 - Exit: any criterion failed triggers the kill switch and returns the loop to its native controller.
173
174 ## Scoring your own pilot
175 Capture the baseline (a period before the controller, or a matched node pool left on your normal autoscaler) and the
    Omni-Compass period or pool with fleet/capture/kube_capture.sh, then:
176 `python pilot/score.py --baseline baseline.csv --omni omni.csv [--idle-w W --dyn-w W]`
177 It reports node-hours and energy per used CPU core-hour, utilisation, pending-pod minutes and HPA shortfall minutes, ea
    ch
178 with a bootstrap 95% interval over hourly blocks. Energy is measured if the captures include power_w. Run long enough
    for at least 24 blocks per side, and compare matched pools at the same time where possible, because traffic changes
    between periods.
179
180 ## Phase 3: Component retirement
181 A decision component is retired only after its loop has passed Phase 2 and a one-at-a-time removal shows no degradation
    (keep-or-remove rule, Manual Chapter 6). Execution and security components are retained.
182
183 ## Reporting
184 All pilot metrics, including failures, are reported in the same format as the benchmark results.
185 """

81  # ----- executive summary
82  P("Executive Summary", H1)
83  P("Omni-Compass is a control engine that sits above Kubernetes. Kubernetes remains the execution layer: it schedules an
    d runs the "
84  "containers, and its autoscalers react to unscheduled work. Omni-Compass is the single authority above it: it reads t
    he machines "
85  "directly, evolves a six-state dynamical model of the stack, sets Kubernetes' scaling targets, owns scale-down, power
    caps, rollback "
86  "authority and routing, and passes every command through a safety shield before execution. Components whose only role
    was to make "
87  "competing control decisions (Terraform as a live capacity controller, separate power agents, the paging path) are re
    tired from the "
88  "control loop. The engine runs in two operator-selected modes: power-protect, which enforces the site power limit, an
    d throughput, which "
89  "applies the same power rules as the native stack.")

6  """
7  EXECUTION CONTRACT
8  -----
9  Run this Python script in a real execution environment.
10 Execute it exactly as written, without modifying parameters, run counts,
11 defaults, random seeds, or logic.
12
13 Capture and return the full raw stdout exactly as printed by the program,
14 including headers, timestamps, availability identifiers, and all summary
15 sections.
16
17 All parameters actually used during execution – including configuration
18 values, runtime constants, sampled parameters, random seeds, and derived
19 settings – are fully emitted in the console output and embedded in all
20 generated artifacts.
21
22 The reported results, classifications, summaries, and artifacts are a
23 direct and exclusive consequence of the parameters used during execution
24 and the declared program logic, and are attributable to no other source,
25 assumption, interpretation, external modification, or post-processing.
26
27 Also return the complete generated release without modification. For a 500-run publication the principal human-readable
   contract is exactly three report families in three formats each: (1) Integrated Master Report PDF/TXT/HTML, (2) seeded
   Technical Referee Sample PDF/TXT/HTML, and (3) Owner / Executive / Commercial / Legal Companion PDF/TXT/HTML. Raw CSV/
   JSONL, manifests, validation registries, claim/theorem ledgers, and evidence artifacts are additional supporting output
   s.
28
29 Do not paraphrase, summarize, reinterpret, omit, infer, or substitute
30 results.
31 -----
32
33 =====
34 DECLARATION HEADER

45 EIGHT-LINE PIECE I MONTE CARLO / RUNGE-KUTTA (RK4) SIMULATION ENGINE
46
47 CERT-10 DWELL QUALIFICATION
48 -----
49 The primary certification rule is ten consecutive same-basin observations.
50 The 20-step horizon remains unchanged. A qualifying CERT-10 streak may begin
51 as late as Step 11 and complete on Step 20. CONVEY-5 may begin as late as
52 Step 16 and confirm on Step 20. These are distinct start and completion
53 bounds. The code asserts both bounds before execution and validates every
54 emitted run row against them.
55
56 CANONICAL SIGNED-BASIN RECONCILIATION
57 -----
58 The canonical Monte Carlo sampler is symmetric on  $U(0)$  in  $[-1, +1]$ .
59 The Step-0 nearest signed basin is declared as the supervisory target
60 before the first RK4 microstep. This preserves the authoritative eight-line
61 Piece I differential equation while making the canonical governed execution
62 directly exercise both +1 and -1 capture. The separate dual-basin suite remains
63 an additional cross-basin disturbance and recovery stress test.
64
65 SPINOR-CLOSURE EXTENSION
66 -----
67 The integrated eight-line Piece I-S core below is the canonical executable form. The spinor extension
68 introduces the phase  $\theta(t) = \omega_B t$  and multiplies line (4) by
69  $\chi(\theta) = \cos(\theta/2)$ , yielding +I at 0 degrees, -I at 360 degrees,
70 and +I at 720 degrees. Line (7) remains the continuous bath law. Line (8) is now executed as
71 a finite-difference companion residual on the generated bath trajectory.
72 The standard 20-step run evaluates the active phase interval it reaches;
73 a dedicated evidence test separately verifies the  $0^\circ/360^\circ/720^\circ$  periodicity.

83
84   Authorship and Ownership:
85   The equations, symbol mappings, governing architecture, stability and
86   conveyance logic, simulation protocols, benchmark mechanisms, reporting
87   structures, documentation, and generated artifacts are proprietary works
88   asserted by The Omni-Compass LLC, except for separately identified
89   third-party materials and public-source references.
90
91   Legal and Filing Status:
92   The Omni-Compass LLC represents that Omni-Compass is subject to United States
93   patent, copyright, trademark, trade-secret, contractual, and other protections,
94   filings, and registrations as applicable. Specific record identifiers are
95   intentionally omitted from these reports. Publicly available records may be
96   searched through the USPTO and U.S. Copyright Office public systems; official
97   records control. Additional information may be requested through
98   www.omni-compass.com and furnished during qualified diligence as appropriate.
99   Access, possession, inspection, execution, or receipt of output grants no
100  implied license, ownership interest, waiver, estoppel, or authorization beyond
101  applicable written terms. All rights reserved.
102
103  -----
104
105  AVAILABILITY, USE LEVELS, AND RIGHTS BOUNDARY
106  -----
107  "Time is of the Essence."
108  The Omni-Compass is available through The Omni-Compass LLC for controlled
109  technical evaluation, research collaboration, pilot integration, strategic
110  engagement, and separately licensed commercial deployment.
111
112  The same rights boundary applies at every use level, including inspection,
113  local execution, simulation, academic or internal research, benchmarking,
114  reproduction, observe-only operation, shadow mode, supervised control,
115  bounded-autopilot operation, hybrid control, direct-to-muscle control,
116  production deployment, embedding, hosted service, productization,
117  monetization, redistribution, and derivative use.
118
119  Public availability or technical access does not make Omni-Compass open
120  source and does not itself authorize commercial use, production deployment,
121  redistribution, sublicensing, removal of ownership notices, or creation or use
122  of derivative implementations. Any permission is limited to the scope of the
123  applicable repository notice, evaluation terms, or executed written agreement.
124  Where non-waivable law provides rights that cannot be restricted, that law
125  controls only to the required extent.
126
127  COMMERCIAL RIGHTS, PRICING, AND CLAIM BOUNDARY
128  -----
129  Commercial use, monetization, production deployment, embedding,
130  productization, paid-service use, customer-facing use, or sustained
131  operational integration requires a separately executed written license and
132  applicable authorization issued by The Omni-Compass LLC. The commercial
133  instrument contemplated by this report is a license, not a sale or transfer of
134  ownership. For preliminary planning, this new-mechanism release uses an
135  introductory, nonbinding benchmark equal to 10% of independently verified and
136  contractually accepted value captured. The value base and resulting amount are
137  company-specific; the percentage, basis, scope, and terms may change and are
138  expected to increase as validation, demand, adoption, authorized reach, support
139  burden, and strategic value increase. Only a definitive executed agreement
140  creates a pricing or licensing obligation. Benchmark dollar figures concern
141  modeled infrastructure operation, staffing, energy, downtime, incident loss,
142  or savings relative to declared comparison baselines; they are not guaranteed
143  customer results or binding commercial terms.
144
145  Numerical execution results are bounded to the disclosed code, configuration,
146  seeds, assumptions, finite horizons, and acceptance predicates. Modeled
147  benchmark, economic, readiness, architectural, originality, and deployment
148  statements are not vendor certification, legal conclusions, investment advice,
149  production guarantees, universal optimality claims, or substitutes for
150  independent validation and domain-specific approval.

207
208 -----
209
210 PIECE I COUPLING ARCHITECTURE
211 -----
212 Closed feedback core: E, U, S.
213 Driven response/observer channels: I_U, B, B_dot.
214 gamma_1 is reserved for compatibility and is inactive in Piece I derivatives.
215 The bath law uses omega_B^2 B, so omega_B has the declared units of angular frequency.
216 Line (7) advances B and B_dot continuously by RK4. Line (8) independently evaluates
217 the discrete bath residual using D^2_hB[n]=(B[n+1]-2B[n]+B[n-1])/h^2 and
218 D_hB[n]=(B[n]-B[n-1])/h; it is a numerical-consistency audit, not a second bath.
219
220 STABILITY / CONVEYANCE / SELF-TUNING PROTOCOL
221 -----
222
223 Macro Step Indexing:
224 Step 0 : Initial sampled state (pre-integration)
225 Step 1 : First completed macro step
226 Max : 20 macro steps per run
227
228 Basin Definition:
229 Basin centers are (+1, -1). A step is in basin if U lies within
230 tolerance of one basin center.
231
232 Born-in-Basin Rule:
233 Basin membership at Step 0 permanently identifies the born-in-basin
234 category. Step 0 counts as the first observation of the same-basin
235 streak. A born-in-basin run is confirmed conveyed after Steps 0, 1, 2, 3,
236 and 4 remain in the same basin. It receives no self-tuning category,
237 but it remains under universal Omni-Compass basin regulation throughout

```

```

238     all 20 macro steps. CERT-10 is earned after ten consecutive same-basin
239     observations, including Step 0 when the run is born in basin.
240
241 Self-Tuning and Universal Regulation:
242     Every run outside both basins at Step 0 is classified as self-tuning
243     applied. That category begins at Step 1. The same nearest-basin
244     Omni-Compass regulation law remains active for every trajectory,
245     including born-in-basin trajectories, throughout the full 200-microstep horizon.
246     Category does not switch the governing regulation off.
247
248 Normal Conveyance and Certification Rules:
249     Every run requires five consecutive same-basin observations for
250     CONVEY-5. For a born-in-basin run these are Steps 0, 1, 2, 3, and 4. For a
251     non-born run the first completed in-basin macro is observation one.
252     The first observation of the qualifying streak is the conveyance entry
253     step and the fifth is the confirmation step. All runs earn CERT-10 only
254     after ten consecutive same-basin observations. The latest CERT-10 streak-start step is 11 and certification may com
255     plete on Step 20;
256     the latest CONVEY-5 streak-start step is 16 and confirmation may complete on Step 20.
257
258 Conveyance Properties:
259     • Conveyance is recorded as an event (non-terminal)
260     • No run may be both born-in-basin and self-tuned
261     • Stability determination is history-dependent

322 =====
323 PUBLICATION, PAGINATION, MATHEMATICS, AND OUTPUT-CONFORMITY CONTRACT
324 -----
325 All principal ReportLab text, table text, Matplotlib labels, chart annotations,
326 and vector-diagram labels are emitted at 11 pt or larger. The report footer is
327 the sole 9 pt exception. Quantitative charts and architecture diagrams use the
328 full available report width and enlarged vertical plotting regions. These are
329 presentation-only changes; equations, numerical parameters, random sampling,
330 RK4 integration, classification predicates, benchmarks, and acceptance logic
331 are unchanged.
332
333 MECHANISM-BOUND REPORTING DOCTRINE
334 =====
335
336 Every numerical table, grid, chart, scorecard, classification, and conclusion
337 emitted by this engine must be computed from one or more of the following
338 executed sources: canonical trajectory rows; recorded state histories
339 (E, U, I_U, S, B, B_dot); sampled trajectory parameters; RK4 derivative
340 evaluations; basin-entry and dwell histories; Line (8) residual evaluations;
341 solver-comparison outputs; ablation outputs; disturbance/stress outputs;
342 compute-benchmark event records; or enterprise benchmark ledgers generated by
343 the declared benchmark mechanisms.
344
345 No decorative referee grade, inferred scientific score, manually assigned
346 quality category, or presentation-only numerical surface is authorized as an
347 engine result. Interpretive prose may identify the exact executed source and
348 claim boundary, but it may not manufacture evidence, substitute a grade for a
349 measurement, or present a non-executed grid as though it were produced by the
350 Omni-Compass mechanism.
